Technical Reference Document	t
by L. Theunissen	

INTRODUCTION

This booklet contains a technical explanation of 8-bit home computer hard- and software based on the MSX-standard, and examples of practical circuitry, as used on the Sony Hit-Bit series microcomputers HB-55 and HB-75. It is intended as an introduction to the MSX-format for engineers and technicians with a solid basic knowledge of microcomputer circuitry in general, and the Z-80 CPV in particular. It will help them understand completely the philosophy behind the MSX-format and the technical solutions used to come to a common, fully interchangeable format that will be used by many computer manufacturers worldwide.

PART I

INTRODUCTION TO MSX

The low end of the home-computer market has now a worldwide standard, called MSX.

MSX, developed by the Microsoft Corporation, is both a hardware and a software standard for 8-bit personal computers.

This implies that all the MSX computer models, marketed by more than a dozen manufacturers, will share the software compatibility attribute.

The hardware in this MSX standard is implemented with three popular chips:

- the Z80 Central Processing Unit (Zilog)

- the 9918 Video Display Processor (Texas Instruments)

- the 8910 Sound Generator (General Instruments)

Included are an Atari joystick interface and specifications for a, read only memory based, cartridge.

The built-in software is written in a new version of Microsoft Basic, called Super-Extended Microsoft Basic. This Basic language has more of a monitor than of an operating system, in that it cannot control disk drives.

But MSX has enough command structure to control the cartridges and cassette-tape recorder that home computers use.

A possible result of this new standard may be that makers of home appliances and TV sets may be prompted to build in standard input/output ports and processors to connect to MSX units, simplifying the introduction of control systems into the home.

Although MSX is originally created as a standard to run ROM-based software, it is now ready in a Disk-Operating-System version. Designed for use with 8-bit Z80 microprocessor hosts, MSX-DOS emulates CP/M-80 calls and contains MS-DOS file formats. In this respect, it is kind of the best of both worlds (8-bit CP/M from Digital Research and 16-bit MS-DOS from Microsoft).

Using Microsoft's words to conclude, MSX means a "Home Personal Computer System for Everybody".

PART II

HARDWARE SPECIFICATIONS

1. Summary of the Hardware Requirements

1-1. Specifications

1-1-1. Required Components

- CPU 4MHz Z-80A compatible

ROM 32K (MSX system software) - Memory RAM minimum 8K (16K* recommended)

Text display capability 40 x 24 (refer to section 2.4) - Screen Display

Graphic 256 x 192 Colour 16

FSK format 1200/2400 Baud - Cassette tape

8 Octave, 3 Voices - Sound

Alphanumeric, Japanese, Graphic (Japanese Version) - Character Set

Alphanumeric, European, Graphic (International

Version).

U.S./Europe, French*, German*, Japanese - Keyboard

Software cartridge, expansion BUS slots - Expansion Slot

1 or 2 - Joystick

1-1-2. Recommended Extensions for U.S./Europe

RAM 64K* total - Memory

- Expansion Slot Second

- Video RF output

* Items with asterisk may not be built-in in the minimum system.

1-1-3. Standardized Optional Extensions*

- Screen Display* 80-Column text

- Clock* Battery backed-up CMOS

- Communication* RS-232

ible

- Printer* 8 bit parallel

2. Components

2-1. LSI

- CPU Z-80 Compatible
CLOCK 3.579545MHz (NTSC Colour Sub Carrier Frequency)
1 WAIT in M1 CYCLE

- VDP TI TMS-9918A Compatible

- PSG GI AY-3-8910 Compatible

- PPI Intel i-8255 Compatible

2-2. Memory

- ROM MSX BASIC 32KB

- RAM 8KB or more

Basic unit has four logical slots, so the total memory space can be expanded up to 256KB. Each logical slot can be expanded to have up to 4 physical slots, or 16 slots. In this case, the total memory space is 1 megabyte.

BASIC ROM occupies address 0 to 7FFF, RAM address starts from FFF and grows downward on the memory map.

Although the BASIC ROM only uses 32K of RAM, the machine needs 64K of RAM for MSX-DOS.

^{*} Items with asterisk may not be built-in in the minimum system.

2-3. Interrupt

- NMI

Not used. See note.

- INT

Accept interrupts from VDP and cartridge. The interrupt is Z-80 mode 1. (Branch to 38H) MSX system software uses interrupt from VDP for timer count. The interval of the interrupt is 60Hz in NTSC and 50Hz in PAL/SECAM version.

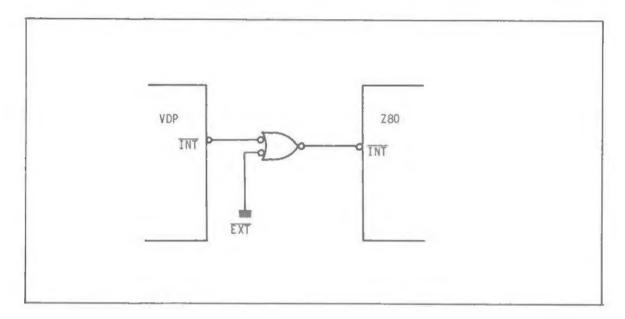

Fig. II-1.

Note: It is not possible to support NMI under MSX-DOS environment because address 66H, which is the entry vector for NMI, is occupied by the FCB data of the DOS.

2-4. Screen Display

- LSI

TI TMS9918A Compatible

- Character set

Alphanumerical + European + Graphic

256 patterns 6 x 8 dots

- Colour

16 colours

- Sprites

32 sprites. Maximum 4 sprites on the same horizontal

line.

MODE		MODE RES.		НО Д	COLOUR	SPRIT	NUMBER OF CHARACTERS

corour	Suggested Value	64 x 40blk	/block		colours		29 x 24
Text	LSI Spec.	256 x 192	6 x 8	256	2 colours out of 16 colours	YES	40 x 24
	Suggested Value	240 x 192					39 x 24

Table II-1. List of Display Modes

Suggested value to use: the 8 pixels from left and right of horizontal are not used by software.

Δ The number of patterns

2-5. Keyboard

- Layout

Refer to figure U.S./European

French German

- Scanning

Software scanning driven by VDP interrupt

- Number of keys

70 plus optional dead key

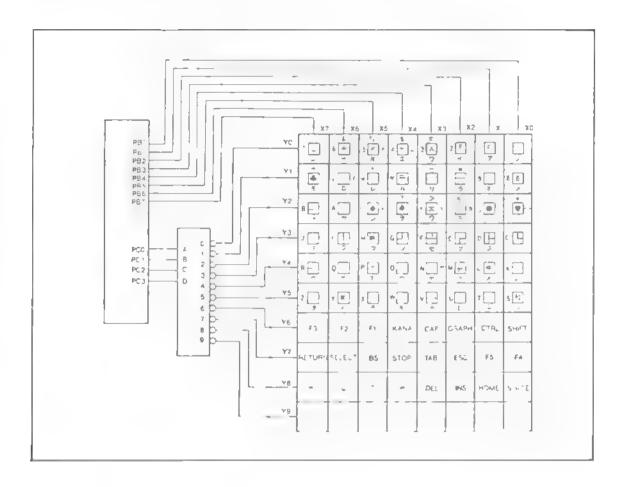

Fig. II-2. Matrix Diagram

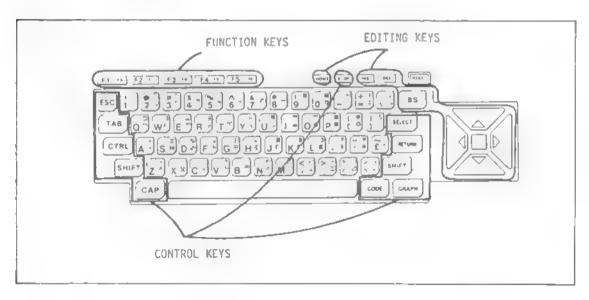

Fig. II-3. Keyboard Layout

The following keyboard diagrams contain an optional dead-key. This dead-key is useful for European accented character input. For example, when one wishes to enter "ā", one must first press the dead-key "^" and then press "a".

The dead-key will not be useful in the U.S. or U.K. Nor will it be useful in France and Germany, where specific French and German keyboards nave been designed which include different dead-keys. Therefore this general dead-key should only be included on machines which will be marketed into minor European countries.

The keyboard diagrams show the dead-key to the left of the carriage return key, but this is probably not a good place for it, because it pushes the carriage return key too far to the right. Manufacturers may place this key where they wish.

2-6. Sound

- LSI GI AY-3-8910 Compatible

- Octave Octaves (3 Voices output)

- Sound Effect Yes

- Software Sound Output 1 bit from output port

- Output Level -5dBm (If the system has output connector)

- Connector RCA-2 pins (If the system has audio output connector)

2-7. Cassette Interface

- Modulation

- Input From the earphone terminal of tape recorder

- Output To the microphone terminal of tape recorder

- Synchronization Asynchronous by the software

- Baud Rate 1200 Baud (1200Hz - 1 wave "0", 2400Hz - 2

waves "1") '(Default) 2400 Baud (2400Hz - 1 wave "0", 4800Hz - 2

waves "1") Change by software

(Tape recorder may have to be specified by the manufacturer when used under 2400 Baud

11000

FSK (Frequency Shift Keying) by the

software

- Demodulation

By the software. The system software automatically detects the baud rate when receiv-

ing the data.

- Motor Control

Table II-6. Signal Pin Illustration (Underlined signals are negative logic)

CS signals imply memory request and read signal. Therefore they cannot be used as chip select for writable devices such as RAMs.

3-3. Condition of Cartridge Connection

3-4. Power Capacity

+5V 300mA/slot +12V 50mA

-12V 50mA

4. Memory

4-1. Memory Map

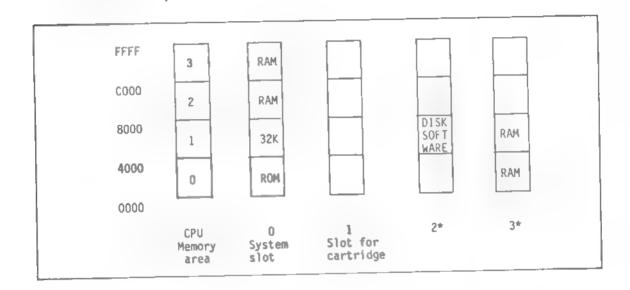

Fig. II-5. Memory Map Example

- MSX BASIC uses the largest available contiguous RAM area that is installed from FFFF to 8000 for its system working RAM area. This can be placed in any slots including expansion slots.
- Slot select register, which is port A of 8255, maps the physical memory space to the logical CPU memory space in 16K byte units (pages). For example, the following value in the slot select register allocates page 0 and 1 from slot 0, page 2 from slot 2 and page 3 from slot 0.

```
- LSB
                           1 0
                     3 2
                 4
MSB -
       7
          6
              5
                 0
                     0
                       0
       0
          0
                           ----- allocate slot O for page O
                          ----- allocate slot 0 for page 1
                        _____ allocate slot 2 for page 2
                          _____ allocate slot 0 for page 3
```

Fig. II-6.

Physical memory is always allocated to the same memory page in the CPU address space. It is not possible to allocate to a different page, like page 3 of slot 3, to page 0 of CPU memory space.

- Minimum system must have two slots, one for system, the other for cartridge.

NOTE:

The word "slot" does not imply that it must have a connector for cartridges, however, a slot for cartridges must have a connector, of course. Refer to APPENDIX C.

- MSX-DOS requires 64K RAM.

W BIT7 - Video select L - TV

5-2. Notes on I/O Address Assignment

- I/O address 80 c FF are assigned for system usage. The empty areas are reserved for system use. Although these addresses are defined here, software should not access those devices directly through the addresses listed above. Every access to the I/O must be done through the BIOS calls. This is to keep software independent from hardware differences. Manufacturers may change some hardware from the standard MSX system but still be able to maintain software compatibility by supporting the hardware

differences within the BIOS, so that the difference can be transparent to software.

The only exception is access to the VDP. Locations 6 and 7 of the MSX system ROM contain read and write addresses of VDP register. The software needing to access VDP very quickly may access VDP directly through those addresses stored in ROM.

- 00 c 7F are free addresses, however when different devices use the same address, they may not be accessed at the same time. Basically, special I/O devices not defined here should be placed in the memory space as memory-mapped I/O. Refer to Appendix B.3.
- # FDC may be placed in I/O space, but it must have a mechanism to disable it and only at the moment when the system accesses the FDC, is it enabled. This makes it possible to have more than one FDC interface in the system to handle different kinds of media.

5-3. 8255 (PPI) Bit Assignment

APPENDIX B

NOTES ON SYSTEM EXPANSION

B-1. RAM Expansion

- The MSX BASIC needs contiguous RAM space starting from FFFF down to 8000. Therefore, additional RAM should be added to existing RAM to form contiguous RAM space.
- If the basic model has only 8K bytes of RAM, it is not possible to add RAM in the slot other than the original 8K in place, because the slot select logic treats memory space in 16K byte units. So an expansion cartridge that has 16K bytes adds only 8K bytes when it is placed at location COOO to FFFF. It is not possible to expand the RAM area by placing it at location 8000 to BFFF because there would be no RAM from COOO to DFFF.
- The BASIC MSX software only uses RAM from 8000 to FFFF, so the RAM installed from 0 to 7FFF cannot be used by it.

B-2. Slot Expansion

- To expand slots, the additional slots are expanded from a primary slot. Primary slots are those slots which are managed by the basic slot select register placed in port A of 8255. Therefore, to select the expanded slot, first select the primary slot to which the expanded slot is connected, and select the desired expansion slot.
- The location of the slot select register for the expanded slots is at memory address FFFF of the primary slot. To make it possible to differentiate this register from ordinary RAM, complement the output of the register. That is, when reading the register, the read data is the complement of the actual value of the register.
- The maximum number of cartridges that can be connected to the cartridge bus is four. Therefore, buffers are necessary to put more than five slots to the system. The control signal that controls the direction of those buffers is BUSDIR. Those devices which send signals to the CPU and are placed in an expanded slot have to send BUSDIR signal as well the change in the direction of the buffer from expanded slots to CPU.

However, for the accesses to memory, it is possible to know the direction of the bus using the slot select signal to the primary slot, memory request signal and read/write signal. So the direction of the buffer should be controlled around the buffer circuitry. So, those cartridges which contain only ROM/RAM do not have to manage BUSDIR signal, which makes them cheap. But those cartridges that contain

some devices which send signals to the CPU, that is, those devices that respond to INP instruction or those devices that are responsible to supply the address in response to the mode 2 of interrupt, must force BUSDIR at "L" level when they send data to the CPU.

B-3. I/O Expansion

- In the Z-80 based system, it is common to place I/O devices in I/O address space. But the MSX sysem design is so flexible and expandable, it is possible to add some I/O devices with cartridge that share same address space. If this is the case, none of those devices can be

accessed properly.

To avoid this situation, it is preferred to place I/O devices in the memory spaces because they are managed by slot select logic and no memory can be accessed simultaneously when they are placed in But the devices placed in memory space cannot be different slots. accessed by the softwares that run in different slots. So those devices that are general to any software such as VDP have to be placed in 1/0 address space. Also in some case, it is cheaper to use I/O address space because only 8 bits address information should be decoded. I/O address space from 80 to FF is defined for those system devices. But the addresses below 7F are left free.

B-4. Sample Circuit of Expanded Slot

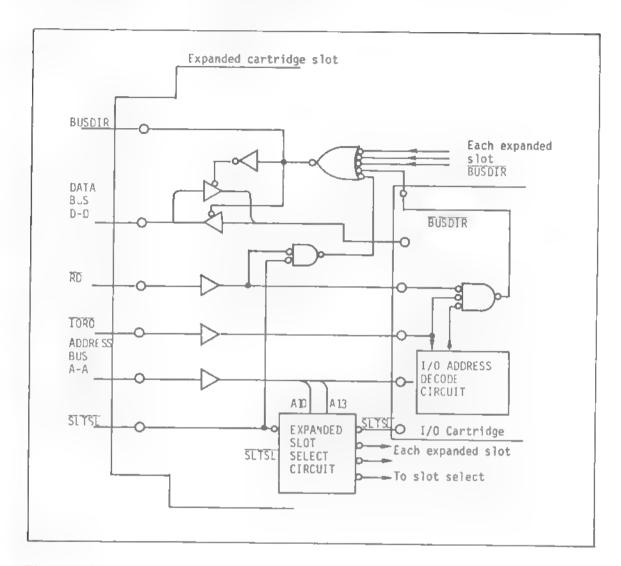

Fig. II-8.

B-5. Slot

- Concept of Slot

For a structure of 64 KB memory space, the concept of slot and memory bank is nearly the same. But CPU can choose the cartidge by the slot number in which it is inserted.

The slot concept is originated from the standpoint of the software, and so, the software is independent to the number of slot that has actual slot opening.

- Advantage of Slot Structure

In the common bus structure, when the memory bank number is even, the device select signal, connected to the bus, cannot distinguish different devices if they use the same memory area, in this case, not only the system becomes out of order, hardware will suffer from deterioration. By using slot select signal to choose each of the device, there will be no such problem, program dueing with two or more devices at the same memory area, can be possible. This is favourable to the flexibility and expandability of the system.

PART III

THE MSX STANDARD CHIP SET

1. The Z80 CPU

1-1. Features

- The instruction set contains 158 instructions. The 78 instructions of the 8080A are included as a subset; 8080A software compatibility is maintained.
- 8MHz, 6MHz, 4MHz and 2.5MHz clocks for the Z80H, Z80B, Z80A and Z80 CPU result in rapid instruction execution with consequent high data throughput.
- The extensive instruction set includes string, bit, byte and word operations. Block searches and block transfers together with indexed and relative addressing result in the most powerful data handling capabilities in the microcomputer industry.

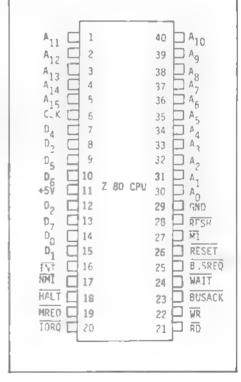

Fig. III-1. Pin Functions

Fig. III-2. Pin Assignments

- The Z80 microprocessors and associated family of peripheral controllers are linked by a vectored interrupt system. This system may be daisy-chained to allow implementation of a priority interrupt scheme. Little, if any, additional logic is required for daisy-chaining.
- Duplicate sets of both general-purpose and flag registers are provided, easing the design and operation of system software through single-context switching, background-foreground programming, and single-level interrupt processing. In addition, two 16-bit index registers facilitate program processing of tables and arrays.
- There are three modes of high-speed interrupt processing: 8080 similar, non-Z80 Family peripheral with or without daisy chain.
- On-chip dynamic memory refresh counter.

1-2. General Description

The Z80, Z80A, Z80B and Z80B CPU's are third-generation single-chip microprocessors with exceptional computational power. They offer higher system throughput and more efficient memory utilization than comparable second- and third-generation microprocessors. The internal registers contain 208 bits of read/write memory that are accessible to the programmer. These registers include two sets of six general-purpose registers which may be used individually as either 8-bit registers or as 16-bit register pairs. In addition, there are two sets of accumulator and flag registers. A group of "Exchange" instructions makes either sets of main or alternate registers accessible to the programmer. The alternate set allows operation in foreground-background mode or it may be reserved for very fast interrupt response.

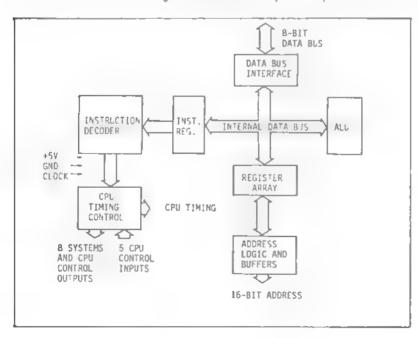

Fig. III-3. Z80 CPU Block Diagram

The Z80 also contains a Stack Pointer, Program Counter, two index registers, a Refresh register (counter), and an Interrupt register. The CPU is easy to incorporate into a system since it requires only a single +5V power source. All output signals are fully decoded and timed to control standard memory or peripheral circuits, and it is supported by an extensive family of peripheral controllers. The internal block diagram (Fig. 111-3) shows the primary functions of the Z80 processors. Subsequent text provides more detail on the Z80 I/O controller family, registers, instruction set, interrupts and daisy chaining, and CPU timing.

1-3. Z80 Microprocessor Family

The Zilog Z80 microprocessor is the central element of a comprehensive microprocessor product family. This family works together in most applications with minimum requirements for additional logic, facilitating the design of efficient and cost-effective microcomputer-based systems.

Zilog has designed five components to provide extensive support for the Z80 microprocessor. These are:

- The PIO (Parallel Input/Output) operates in both data-byte I/O transfer mode (with handshaking) and in bit mode (without handshaking). The PIO may be configured to interface with standard parallel peripheral devices such as printers, tape punchers, and keyboards.
- The CTC (Counter/Timer Circuit) features four programmable 8-bit counter/timers, each of which has an 8-bit prescaler. Each of the four channels may be configured to operate in either counter or timer mode.
- The DMA (Direct Memory Access) controller provides dual port data transfer operations and the ability to terminate data transfer as a result of a pattern match.
- The SIO (Serial Input/Output) controller offers two channels. It is capable of operating in a variety of programmable modes for both synchronous and asynchronous communication, including Bi-Sync and SDLC.
- The DART (Dual Asynchronous Receiver/Transmitter) device provides low cost asynchronous serial communication. It has two channels and a full modem control interface.

1-4. Z80 CPU Registers

Fig. III-4, shows three groups of registers within the Z80 CPU. The first group consists of duplicate sets of 8-bit registers: a principal set and an alternate set (designated by '[prime], e.g., A'). Both sets consist of the Accumulator Register, the Flag Register, and six general-purpose registers. Transfer of data between these duplicate sets of registers is accomplished by use of "Exchange" instructions. The result is faster response to interrupts and easy, efficient implementation of such versatile programming techniques as background-foreground data processing. The second set of registers consists of six registers with assigned functions. These are the I (Interrupt Register), the R (Refresh Register), the IX and IY (Index Registers), the SP (Stack Pointer), and the PC (Program Counter). The third group consists of two interrupt status flip-flops, plus an additional pair of flip-flops which assists in identifying the interrupt mode at any particular time.

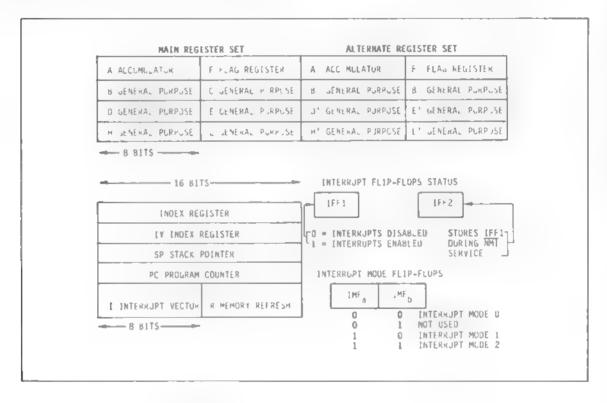

Fig. III-4. CPU Registers

1-5. Interrupts: General Operation

The CPU accepts two interrupt input signals: NMI and INT. The NMI is a non-maskable interrupt and has the highest priority. INT is a lower priority interrupt and it requires that interrupts be enabled in software in order to operate. INT can be connected to multiple peripheral devices in a wired-OR configuration.

The Z80 has a single response mode for interrupt service for the non-maskable interrupt. The maskable interrupt, INT, has three programmable response modes available.

These are:

- Mode 0 - similar to the 8080 microprocessor

- Mode 1 - Peripheral Interrupt service, for use with non-8080/Z80 systems.

 Mode 2 - A vectored interrupt scheme, usually daisy-chained, for use with Z80 Family and compatible peripheral devices.

The CPU services interrupts by sampling the NMI and INT signals at the rising edge of the last clock of an instruction. Further interrupt service processing depends upon the type of interrupt that was detected. Details on interrupt responses are shown in the CPU Timing Section

Non-Maskable Interrupt (NMI).

The non-maskable interrupt cannot be disabled by program control and therefore will be accepted at all times by the CPU. NMI is usually reserved for servicing only the highest priority type interrupts, such as that for orderly shut-down after power failure has been detected. After recognition of the NMI signal (providing BUSREQ is not active), the CPU jumps to restart location 0066H. Normally, software starting at this address contains the interrupt service routing.

Maskable Interrupt (INT).

Regardless of the interrupt mode set by the user, the Z80 response to a maskable interrupt input follows a common timing cycle. After the interrupt has been detected by the CPU (provided that interrupts are enabled and BUSKEQ is not active) a special interrupt processing cycle begins. This is a special fetch (M1) cycle in which IORQ becomes active rather than MREQ, as in normal M1 cycle. In addition, this special M1 cycle is automatically extended by two WAIT states, to allow for the time required to acknowledge the interrupt request.

Mode O Interrupt Operation

This mode is similar to the 8080 microprocessor interrupt service procedures. The interrupting device places an instruction on the data bus. This is normally a Restart instruction, which will initiate a call to the selected one of eight restart locations in page zero of memory. Unlike the 8080, the Z80 CPU responds to the Call instruction with only one interrupt acknowledge cycle followed by two memory read cycles.

Mode 1 Interrupt Operation.

Mode 1 operation is very similar to that for the NMI. The principal difference is that the Mode 1 interrupt has a restart location of 0038H only.

Mode 2 Interrupt Operation.

This interrupt mode has been designed to utilize most effectively the capabilities of the Z80 microprocessor and its associated peripheral family. The interrupting peripheral device selects the starting address of the interrupt service routine. It does this by placing an 8-bit vector on the data bus during the interrupt acknowledge cycle. The CPU forms a pointer using this byte as the lower 8-bits and the contents of

the I register as the upper 8-bits. This points to an entry in a table of addresses for interrupt service routines. The CPU then jumps to the routine at that address. This flexibility in selecting the interrupt service routine address allows the peripheral device to use several different types of service routines. These routines may be located at any available location in memory. Since the interrupting device supplies the low-order byte of the 2-byte vector, bit 0 (A_0) must be a zero.

Interrupt Priority (Daisy Chaining and Nested Interrupts).

The interrupt priority of each peripheral device is determined by its physical location within a daisy-chain configuration. Each device in the chain has an interrupt enable input line (IEI) and an interrupt enable output line (IEO), which is fed to the next lower priority device. The first device in the daisy chain has its IEI input hardwired to a High level. The first device has highest priority, while each succeeding device has a corresponding lower priority. This arrangement permits the CPL to select the highest priority interrupt from several simultaneously interrupting peripherals.

The interrupting device disables its IEO line to the next lower priority peripheral until it has been serviced. After servicing, its IEO line is raised, allowing lower priority peripherals to demand interrupt servicing.

The Z80 CPU will nest (queue) any pending interrupts or interrupts received while a selected peripheral is being serviced.

Interrupt Enable/Disable Operation.

Two flip-flops, IFF₁ and IFF₂, referred to in the register description are used to signal the CPU interrupt status. For more details, refer to the Z80 CPU Technical Manual and Z80 Assembly Language Manual.

Action	IFF ₁	IFF ₂	Comments
CPU Reset	0	0	Maskable interrupt INT disabled
Ol Instruction execution	0	0	Maskable interrupt IMT disabled
IE instruction execution	1	1	Maskable interrupt INT enabled
LD A, I instruction execution	v		IFF ₂ - Parity flag
LD A ,R instruction execution	*		IFF ₁ - Parity flag
Accept NMI	0	IFF ₁	<pre>1FF₁ - 1FF₂ {Maskable interrupt INT disabled,</pre>
RETN instruction	IFF ₂	•	1FF ₂ - IFF ₁
execution			at completion of an NHI service routine

Table III-1. State of Flip-Flops

1-6. Instruction Set

The Z80 microprocessor has one of the most powerful and versatile instruction sets available in any 8-bit microprocessor. It includes such unique operations as a block move for fast efficient data transfers within memory or between memory and I/O. It also allows operations on any bit in any location in memory.

The following is a summary of the Z80 instruction set and shows the assembly language mnemonic, the operation, the flag status, and gives comments on each instruction. The Z80 CPU Technical Manual (03-0029-01) and Assembly Language Programming Manual (03-0002-01) contain significantly more details for programming use.

The instructions are divided into the following categories:

- 8-bit loads
- 16-bit loads
- Exchanges, block transfers, and searches
- 8-bit arithmetic and logic operations
- General-purpose arithmetic and CPU control
- 16-bit arithmetic operations
- Rotates and shifts
- Bit set, reset, and test operations
- Jumps
- Calls, returns, and restarts
- Input and output operations

A variety of addressing modes are implemented to permit efficient and fast data transfer between various registers, memory locations, and input/output devices. These addressing modes include:

- Immediate
- Immediate extended
- Modified page zero
- Relative
- Extended
- Indexed
- Register
- Register indirect
- Implied
- Bit

1-7. Pin Descriptions

A₀ - A₁₅-

Address Bus (output, active High, 3-state). A_0 - A_{15} for a 16-bit address bus. The Address Bus provides the address for memory data bus exchanges (up to 64K bytes) and for I/O device exchanges.

BUSACK. Bus Acknowledge (output, active Low).
Bus Acknowledge indicates to the requesting device that the CPU address bus, data bus, and control signals MREQ, IORQ, RD, and WR have entered their high-impedance states. The external circuitry can now control these lines.

BUSREQ. Bus Request (input, active Low).
Bus Request has a higher priority than NMI and is always recognized at the end of the current machine-cycle. BUSREQ forces the CPU address bus, data bus, and control signals MREQ, IORQ, RD and WR to go to a high-impedance state so that other devices can control these lines.
BUSREQ is normally wire-ORed and requires an external pullup for these applications. Extended BUSREQ periods due to extensive DMA operations can prevent the CPU from properly refreshing dynamic RAMs.

 $D_0 - D_7$. Data Bus (input/output, active High, 3-state).

 D_0 - D_7 constitute an 8-bit bidirectional data bus, used for data exchanges with memory and I/O.

HALT. Halt State (output, active Low).
HALT indicates that the CPU has executed a Halt instruction and is awaiting either a non-maskable or a maskable interrupt (with the mask enabled) before operation can resume.
While halted, the CPU executes NOPs to maintain memory refresh.

INT. Interrupt Request (input, active Low). Interrupt Request is generated by I/O devices. The CPU honors a request at the end of the current instruction if the internal software controlled interrupt enable flip-flop (IFF) is enabled. INT is normally wire-ORed and requires an external pullup for these applications.

IORQ. Input/Output Request (output, active Low, 3-state). IORQ indicates that the lower half of the address bus holds a valid I/O address for an I/O read or write operation. IORQ is also generated concurrently with M1 during an interrupt acknowledge cycle to indicate that an interrupt response vector can be placed on the data bus.

M1. Machine Cycle One (output, active Low).
M1, together with MREQ, indicates that the current machine cycle is the opcode fetch cycle of an instruction execution. M1, together with IORQ, indicates an interrupt acknowledge cycle.

MREQ. Memory Request (output, active Low, 3-state). MREQ indicates that the address bus holds a valid address for a memory read or memory write operation.

NMI. Non-Maskable Interrupt (input, negative edge-triggered). NMI has a higher priority than INT. NMI is always recognized at the end of the current instruction, independent of the status of the interrupt enable flip-flop, and automatically forces the CPU to restart at location 0066H.

RD. Read (output, active Low, 3-state). RD indicates that the CPU wants to read data from memory or an I/O device. The addressed I/O device or memory should use this signal to gate data onto the CPU data bus.

RESET. Reset (input, active Low).
RESET initializes the CPU as follows: it resets the interrupt enable flip-flop, clears the PC and Registers I and R, and sets the interrupt status to Mode O. During reset time, the address and data bus go to a high-impedance state, and all control output signals go to the inactive state.

Note that RESET must be active for a minimum of three full clock cycles before the reset operation is complete.

RFSH. Refresh (output, active Low).
RFSH, together with MREQ, indicates that the lower seven bits of the system's address bus can be used as a refresh address to the system's dynamic memories.

WAIT. Wait (input, active Low).
WAIT indicates to the CPU that the addressed memory or I/O devices are
not ready for a data transfer. The CPU continues to enter a Wait state
as long as this signal is active. Extended wAIT periods can prevent the
CPU from refreshing dynamic memory properly.

WR. Write (output, active low, 3-state). WR indicates that the CPU data bus holds valid data to be stored at the addressed memory or I/O location.

1-8. CPU Timing

The Z80 CPU executes instructions by proceeding through a specific sequence of operations:

- Memory read or write
- I/O device read or write
- Interrupt acknowledge

The basic clock period is referred to as a T time of cycle, and three or more T cycles make up a machine cycle (M1, M2 or M3 for instance). Machine cycles can be extended either by the CPU automatically inserting one or more Wait states or by insertion of one or more Wait states by the user.

2. The 8255 PPI

2-1. Description

This is a family of general-purpose programmable input/output devices designed for use with the M5L 8085A 8-bit parallel CPU as input/output ports. These devices are fabricated using N-channel silicon-gate ED-MOS technology for a single supply voltage. They are simple input and output interfaces for TTL circuits, having 24 input/output pins which correspond to three 8-bit input/output ports.

2-2. Features

- 24 programmable I/O pins
- Single 5V supply voltage
- TTL-compatible I_{O1} = 2.5mA (max)
- Fully compatible with MELPS 8 microprocessor series
- Direct bit set/reset capability
- Interchangeable with Intel's 8255A in terms of function, electrical characteristics and pin configuration.

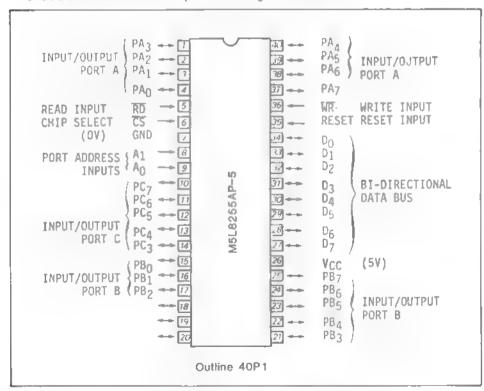

Fig. III-5. Pin Configuration

2-3. Application

- Input/output for MELPS 8/85 microprocessor

2-4. Function

These PPIs have 24 input/output pins which may be individually programmed in two 12-bit groups A and B with mode control commands from a CPU. They are used in three major modes of operation, mode 0, mode 1 and mode 2.

Operating in mode 0, each group of 12 pins may be programmed in sets of 4 to be inputs or outputs. In mode 1, the 24 I/O terminals may be programmed in two 12-bit groups, group A and B. Each group contains one 8-bit data port, which may be programmed to serve as input or output, and one 4-bit control port used for handshaking and interrupt control signals. Mode 2 is used with group A only, as one 8-bit bidirectional bus port and one 5-bit control port.

Bit set/reset is controlled by CPU. A high-level reset input (RESET) clears all internal registers, and all ports are set to the input mode (high-impedance state).

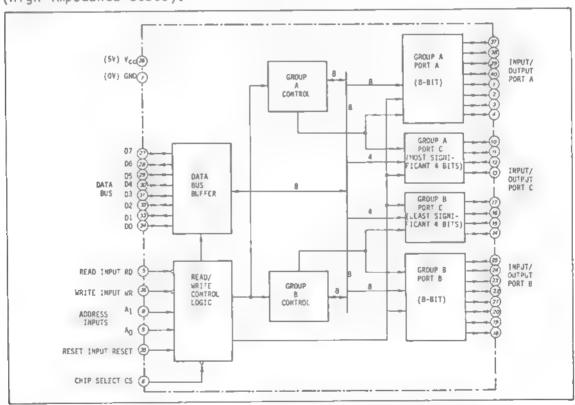

Fig. III-6. Block Diagram

2-5. Functional Description

Data Bus Buffer

This three-state, bidirectional, eight-bit buffer is used to transfer the data when an input or output instruction is executed by the CPU. Control words and status information are also transferred through the data bus buffer.

Read/Write

The function of this block is to control transfers of both data and control words. It accepts the address signals (A_0 , A_1 , CS) from the CPU I/O control bus outputs (RD, WR) from the system controller, and RESET signals, and then issues commands to both of the control groups in the PPI.

CS (Chip-Select) Input

At low-level, the communication between the PPI and the CPU is enabled. While at high-level, the data bus is kept in the high-impedance state, so that commands from the CPU are ignored. Then the previous data is kept at the output port.

RD (Read) Input

At low-level, the status or data at the port is transferred to the CPU from the PPI. In essence, it allows the CPU to read data from the PPI.

WR (Write) Input

At low-level, the data or control words are transferred from the CPU and written in the PPI.

An, An (Port Address) Input

These input signals are used to select one of the three ports: port A, port B, and port C, or the control register. They are normally connected to the least significant two bits of the address bus.

RESET (Reset) Input

At high-level, all internal registers, including the control register, are cleared. Then all ports are set to the input mode (high-impedance state).

Group A and Group B Control

Accepting commands from the read/write control logic, the control blocks (Group A, Group B) receive 8-bit control words from the internal data bus and issue the proper commands for the associated ports. Control group A is associated with port A and the four high-order bits of port C. Control group B is associated with port B and the four low-order bits of port C. The control register, which stores control words, can only be written into.

Port A, Port B and Port C

The PPI contains three 8-bit ports whose modes and input/output settings are programmed by the system software.

Port A has an output latch/buffer and an input latch. Port B has an I/O latch/buffer and an input buffer. Port C can be divided into two 4-bit ports which can be used as ports for control signals for port A and port B. The basic operations are shown in Table III-2.

A ₁	A _O	cs	RD	WR	Operation
0_	0	0	0	11	Data bus-Port A
0	1	0	0	1	Data bus Port B
1 _	0	0	0	1	Data bus-Port C
0	0	0	1	0	Port A - Data bus
0	1	0	1	0	Port 8 - Data bus
1	0	0	1	0	Port C - Data bus
1	1	0	1	0	Control register — Data bus
Х	Х	1	x	X	Data bus is in high impedance state
1	1	0	0	1	Illegal condition

Table III-2. Basic Operations

Where "0" indicates low level "1" indicates high level

Bit Set/Reset

When port C is used as an output port, any one bit of the eight bits can be set (high) or reset (low) by a control word from the CPU. This bit set/reset can be operated in the same way as the mode set, but the control word format is different. This operation is also used for INTE set/reset in mode 1 and 2.

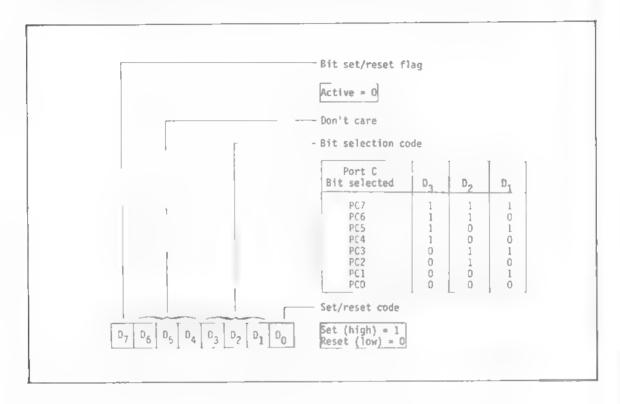

Fig. III-7. Control Word Format for Port C Set/Reset

3. The TMS 9918 VDP

3-1. Introduction

3-1-1. Description

The TMS9918A/9928A/9929A video display processors (VDP) are N-channel MOS LSI devices used in video systems where data display on a raster-scanned home colour television set or colour monitor is desired. These devices generate all necessary video, control, and synchronization signals and also control the storage, and refresh of display data in the dynamic screen refresh memory. The interfaces to the microprocessor, refresh memory, and the TV require a minimum of additional electronics for the TMS9918A.

In Section 3-4, there is a list of acronyms and a glossary of terms used in this manual.

The TMS9928A/9929A VDPs are functionally identical to the TMS9918A except that the NTSC colour encoding circuitry has been removed and replaced with luminance and colour difference signals. The TMS9918A is pin-for-pin compatible with the TMS9928A/9929A, except for three pins, the composite video output, the external video input and the CPU clock output. These pins are replaced with the Black/White luminance and composite sync (Y) output and two colour difference pins, Blue (B-Y) and Red (R-Y) outputs, respectively. The colour difference outputs allow the user to generate Red-Green-Blue (R-G-B) drive for direct colour gun control, or composite video for use with NTSC or PAL video colour monitor. However, to connect these three outputs to a R-G-B or monitor requires additional R-G-B or encoder circuitry.

The TMS9918A/9928A have a 525-line format for U.S. televisions while the TMS9929A has a 625-line format for use with the European PAL system.

The VDP has four video display modes: Graphics I, Graphics II, Multicolour and Text mode. The text mode provides twenty-four 40-character rows in two colours and is intended to maximize the capacity of the TV screen to display alphanumeric characters. The Multicolour mode provides an unrestricted 64 x 48 colour-dot display employing 15 colours plus transparent. The Graphics II mode is an enhancement of Graphics I mode, allowing it to generate more complex colour and pattern displays. The four video display modes are described in detail in Section 3-2-4.

The video display consists of 35 planes: external VDP, backdrop, pattern plane, and 32 sprite Planes. The planes are vertically stacked with the external VDP being the bottom or innermost plane. The backdrop plane is the next plane followed by the pattern plane that contains Graphics I and Graphics II patterns with the 32 Sprite Planes as the top planes.

The TMS9918A/9928A/9929A VDPs use either a 4K, 8K, or 16K-type low-cost dynamic memory (TMS4027, TMS4108, TMS4116) for storage of the display parameters.

The TMS9918A, TMS9928A, and TMS9929A interface identically to the host microprocessor making them software compatible. Thus, all references to VDP in this document apply to all three devices, except where noted.

3-1-2. Features

 Single-chip solution for interfacing colour TVs (excluding Random-Access Memory (RAM) and Radio Frequency (RF) modulator (TMS9918A only)

256 x 192 resolution on TV screen
 15 unique colours plus transparent

- General 8-bit bidirectional interface to Central Processor Unit (CPU)
- Direct wiring to 4K, 8K or 16K dynamic RAM memories Automatic and transparent refresh of dynamic RAMs

- Multiple VDP systems capability

- External VDP input capability (TMS9918A only)

- Composite video output (TMS9918A only)

- Unique planar representation for 3D simulation

- Standard 40-pin package

- Colour difference outputs allow RGB drive - TMS9928A/9929A

3-1-3. Typical Applications

- Colour computer terminals
- Home computers

- Drafting/design aids

- Industrial process monitoring
- Home educational systems

- Animation aids

- European 625-line TV (TMS9929A only)

The following example of a typical application may help introduce the user to the TMS9918A VDP. Figure III-6 is a block diagram of a typical application. Each of the concepts presented in the example is described more fully in later sections of this manual.

The VDP basically has three interfaces: CPU, colour monitor, and dynamic refresh RAM (VRAM), the contents of which define the TV image. The TMS9918A also has eight write-only registers and a read-only status register.

The VDP communicates with the CPU via an 8-bit bidirectional data bus. Three control lines, decoded from the CPU address and enable lines, determine interpretation of the bus. Through the bus, the CPU can write to VRAM, read from VRAM, write to VDP registers, and read the VDP status. The VDP also generates an interrupt signal after every refresh of the TV display.

The dynamic RAM interface consists of direct wiring of eight 4K x 1.8K x 1 or 16K x 1 dynamic RAS/CAS-type RAMs to the VDP. The amount of RAM required is dependent upon the features selected for use in the application.

The interface to the monitor can consist of either wiring the TMS9918A's composite video output pin (suitably buffered) to the input of a colour or black-and-white monitor, or using an appropriate RF modulator to feed the signal into a TV antenna terminal. The TMS9928A/9929A require additional encoder circuitry to interface to a RGB or to a composite video monitor.

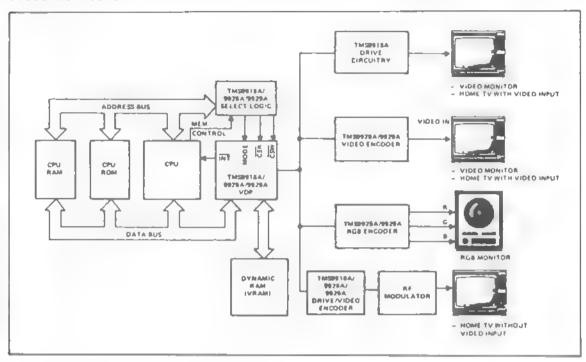

Fig. III-8. System Block Diagram

The VDP operates in four modes and each one can affect the way the VRAM is mapped onto the television screen. In Graphics I and II modes, characters are mapped onto the screen in 8 x 8 pixel blocks yielding 24 lines of 32 blocks (pattern positions) each. In Text mode, there are 24 lines of 40 blocks, each of which is 6 - 8 pixels. In Multicolour mode, there are 48 lines of 64 blocks, each of which is composed of 4 x 4 picture elements (pixels), all of one solid colour. In addition to these, sprites can be superimposed onto the television image in Graphics I, II, and Multicolour mode. Furthermore, signals entering the TMS9918A through the external VDP input can be used as a background to the TMS9918A.

ACRONYMS AND GLOSSARY

B-Y	Blue colour difference output
COMVID	Contains luminance, chrominance and all sync pulse
(Composite Video)	necessary for horizontal and vertical timing
CAS	Column Address Strobe
CPU	Central Processor Unit
CSR	CPU from VDP read select
CSM	CPU to VDP write select
CPULCLK	XTAL - 3
GROMCLK	XTAL - 24

LSB Least Significant Bit LSI Large Scale Integration MOS Metal Oxide Semiconductor MHz

Megahertz

MSB Most Significant Bit

NTSC National | Television Standards Committee which specifies television signal standards for the USA.

PAŁ Phase Alternating Line

Pixel Picture Element - the smallest point on the TV screen

that can be independently controlled.

RAM Random-Access Memory RAS Row-Address Strobe

RASTER The area in which an image is reproduced

RF Radio Frequency R-G-B Red-Green-Blue ROM Read-Only Memory

R/W Read/Write

R-Y Red Colour difference Output

> Y coordinate and whose position can therefore be controlled by that coordinate with a positional

resolution of one pixel. Video Display Processor

VDP. **VRAH** Video RAM, refers to the dynamic RAMs that connect to

the VDP and whose contents define the TV image.

¥ Black/white luminance and composite sync.

3-2. Architecture

The TMS9918A video display processor (VDP) is designed to provide a simple interface between a microprocessor and a raster-scanned colour television. The TMS9928A/9929A VDP's are designed as a simple interface between a microprocessor, and R-G-B monitor or video encoder which produces the video monitor. Fig. III-9 is a block diagram of the major portions of the VDP architecture interfaces to the VDP, CPU, VRAM and colour television.

3-2-1. CPU Interface

The VDP interface to the CPU using an 8-bit bidirectional data bus, three control lines, and an interrupt is shown in figure III-10. Through this interface the CPU can conduct four operations:

- (1) Write data bytes to VRAM
- (2) Read data bytes from VRAM
- (3) Write to one of the eight VDP write-only registers
- (4) Read the VDP Status Register

Each of these operations requires one or more data transfers to take place over the CPU/VDP data bus interface. The interpretation of the data transfer is determined by the three control lines of the VDP.

BUTTE

The CPU can communicate with the VDP simultaneously and asynchronously with the VDP's TV screen refresh operations. The VDP performs memory management and allows periodic intervals of CPU access to VRAM even in the middle of a raster scan.

3-2-1-1. CPU Interface Control Signals

The type and direction of data transfers are controlled by the CSW, CSR, and MODE inputs CSW is the CPU to VDP write select. When it is active (low), the eight bits on CDO - CD7 are strobed into the VDP. CSR is the CPU from VDP read select. When it is active (low), the VDP outputs eight bits on CDO-CD7 to the CPU. CSW and CSR should never be simultaneously low at the same time. If both are low, the VDP outputs data on CDQ-CD7 and latches in invalid data.

MODE determines the source or destination of a read or write data transfer. MODE is normally tied to a CPU low order address line (Al4 for TMS9900).

3-2-1-2. CPU Write to VDP Register

The VDP has eight write-only registers and one read-only status register. The write-only registers control the VDP operation and determine the way in which VRAM is allocated. The status register contains interrupt, sprite coincidence and fifth sprite status flags.

Each of the eight VDP write-only registers can be loaded using two 8-bit data transfers from the CPU. Table III-3 describes the required format for the two bytes. The first byte transferred is the data byte, and the second byte transferred controls the destination. The MSB of the second byte must be a 1. The next four bits are Os, and the lowest three bits make up the destination register number. The MODE input is high for both byte transfers.

To rewrite the data in an internal register after a byte of data has already been loaded, the status register must be read so that internal CPU interface logic is reinitialized and will accept the next byte as data and not as a register destination. This situation may be encountered in interrupt-driven program environments. Whenever the status of VDP write parameters is in question, this procedure should be used.

NOTE

The CPU address is destroyed by writing to the VDP register.

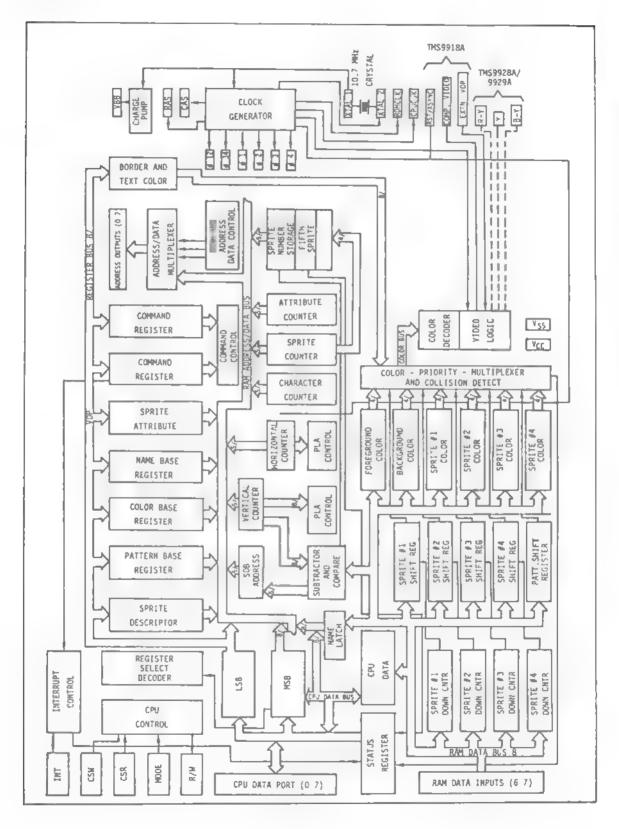

Fig. III-9. VDP Block Diagram

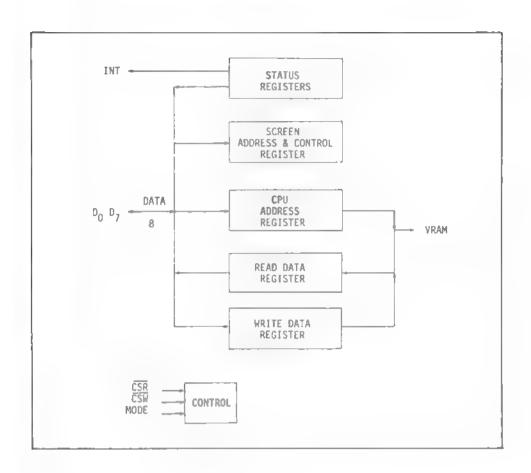

Fig. III-10. VDP to CPU Interface

3-2-1-3. CPU Write to VRAM

The CPU transfers data to the VRAM through the VDP using a 14-bit autoincrementing address register. The address register setup requires 2-byte transfers. A 1-byte transfer is then required to write the data to the addressed VRAM byte. The address register is then autoincremented. Sequential VRAM writes require only 1-byte transfers since the address register is already set up. During setup of the address register, the two MSB's of the second address byte must be 0 and 1 respectively. MODE is high for both address transfers and low for the data transfer. CSW is used in all transfers to strobe the 8 bits into the VDP. See Table III-3.

				BI	Г				į		
OPERATION	0	1	2	3	4	5	6	7	CSW	CSR	MODE
WRITE TO VDP REGISTER									1		
BYTE 1 DATA WRITE	D _O	D_1	02	\mathfrak{d}_3	D_4	05	D ₆	D ₇	0	1	1

Table III-3. CPU/VDP Data Transfers

3-2-1-4. CPU Read from VDP Status Register

The CPU can read the contents of the status register with a single-byte transfer. MODE is high for the transfer. CSR is used to signal the VDP that a read operation is required.

3-2-1-5. CPU Read from VRAM

The CPU reads from the VRAM through the VDP using the autoincrementing address register. A 1-byte transfer is then required to read the data from the addressed VRAM byte. The address register is then autoincremented. Sequential VRAM data reads require only a 1-byte transfer since the address register is already set up. During setup of the address register, the two MSBs of the second address byte must be 0. By setting up the address this way, a read cycle to VRAM is initiated transfers and low for the data transfers. The VDP requires approximately 8 microseconds to fetch the VRAM byte following the last data transfer and 2 microseconds following address setup.

The CPU interacts with VRAM memory through the VDP. The amount of time necessary for the CPU to transfer a byte of data to or from VRAM memory can vary from 2 to 8 microseconds. Once the VDP has been told to read or write a byte of data to or from VRAM it takes approximately 2 microseconds until the VDP is ready to make the data transfer. In addition to this 2 microsecond delay, the VDP must wait for a CPU address window; i.e., the period of time when the VDP is not occupied with memory refresh or screen display and is available to read or write data.

The worst case time between windows occurs during the Graphics I or Graphics II mode when sprites are being used. During the active display. CPU windows occur once every 16 memory cycles giving a maximum delay of 6 microseconds (a memory cycle takes about 372 nanoseconds). In the Text mode the CPU windows occur at least once out of every three memory cycles or a worst case delay of about 1.1 microseconds. Finally, in the Multicolour mode, CPU windows occur at least once out of every four memory cycles.

If the user needs to access memory in 2 microseconds, two situations occur where the time waiting for an access window is effectively zero. Both of these are independent of the display mode being used.

The first situation occurs when the blank bit of register 1 is 0. With this bit low, the entire screen will show only border colour and the VDP does not have to wait for a CPU access window at any time.

The second situation occurs when the VDP is in the vertical refresh mode. The VDP issues an interrupt output at the end of each active area. This signal indicates that the VDP is entering the vertical refresh mode and that for the next 4.3 milliseconds there is no waiting for an access window. If the user wants the CPU to access memory during this interval, it is necessary for the controlling CPU to monitor the interrupt output of the VDP (the CPU can either poll this output to use it as an interrupt input).

The programme that monitors the interrupt output must allow for its own delays in responding to the interrupt signal and recognize how much time it has left during the 4300 microsecond refresh period. The CPU must-write a 1 to the interrupt enabler bit of Register 1 in order to enable the interrupt for each frame, and then read the status register each time an interrupt is issued to clear the interrupt output. A summary of these delay times is presented in Table III-4.

CONDITION	MODE	VDP DELAY	TIME WAITING FOR AN ACCESS WINDOW	TOTAL TIME
Active Display Area	Text	2 µs	0 - 1.1 μs	2 - 3.1 µs
Active Display Area	Graphics I. II	2 μς	0 - 5.95 μs	2 - 8 µs
4300 µs after Ver- tical Interrupt Signal	A11	2 µs	0 µs	2 µs
Register I Blank Bit O	ATT	2 μs	0 με	Z µs
Active Display Area	Multi- colour	2 µs	0 - 1.5 µs	2 - 3.5 p

Table III-4. Memory Access Delay Times

3-2-1-6. VDP-Interrupt

The VDP INT output pin is used to generate an interrupt at the end of each active display scan, which is about every 1/60 second for the TMS9918A/9928A and 1/50 second for the TMS9929A. The INT output is active when the Interrupt Enable bit (IE) in VDP Register 1 is a 1 and

the F bit of the status register is a 1. Interrupts are cleared when the status register is read.

3-2-1-7. VDP Initialization

The VDP is externally intitialized whenever the RESET input is active (low) and must be held low for a minimum of 3 microseconds. The external reset synchronizes all clocks with its falling edge, sets the horizontal and vertical counters to known states, and clears VDP registers 0 and 1. The video display is automatically blanked since the BLANK bit in VDP register 1 becomes a 0. The VDP, however, continues to refresh the VRAM even though the display is blanked. While the RESET line is active, the VDP does not refresh the VRAM.

3-2-2. Write-Only Registers

The eight VDP write-only registers are shown in Fig. III-9. They are loaded by the CPU as described in Section b) Registers 0 and 1 contain flags to enable or disable various VDP features and modes. Registers 2 through 6 contain values that specify starting locations of various sub-blocks of VRAM. The definitions of these sub-blocks are described in section 3-2-4. Register 7 is used to define backdrop and text colours.

Each register is described in the following paragraphs.

3-2-2-1. Register 0

Register O contains two VDP option control bits. All other bits are reserved for future use and must be Os.

BIT 6 M3 (mode bit 3) (see section 3-2-3-2, for table and description)

BIT 7 External VDP enable/disable
O disables external VDP input
1 enables external VDP input

RUTE

Enabling bit 7 in the TMS9928A/9929A causes A-Y and B-Y to go to the sync level only when all planes in front of the pixel under question are transparent.

3-2-2. Register 1 (contains 8 VDP option control bits)

BIT 0 4/16K selection O selects 4027 RAM operation 1 selects 4108/4116 RAM operation

```
BIT 1
          BLANK enable/disable
                   O causes the active display area to blank
                   1 enables the active display
                   Blanking causes the display to show border colour only.
BIT 2
          IE (Interrupt Enable)
                   O disables VDP interrupt
                   1 enables VDP interrupt
BIT 3, 4 M1, M2 (mode 1 and 2)
          M1, M2 and M3 determine the operating mode of the VDP:
                             M2
                   М1
                                        M3
                   0
                                               Graphics I mode
                              0
                                        0
                                               Graphics II mode
                   0
                              0
                                        1
                   Ô
                                        0
                                               Multicolour mode
                              1
                              0
                                        n
                                               Text mode
BIT 5
          Reserved
BIT 6
          Size (sprite size select)
                   O selects Size O sprites (8 x 8 bit)
                   1 selects Size 1 sprites (16 x 16 bits)
BIT 7
          MAG (Magnification option for sprites)
                   O selects MAGO sprites (1x)
```

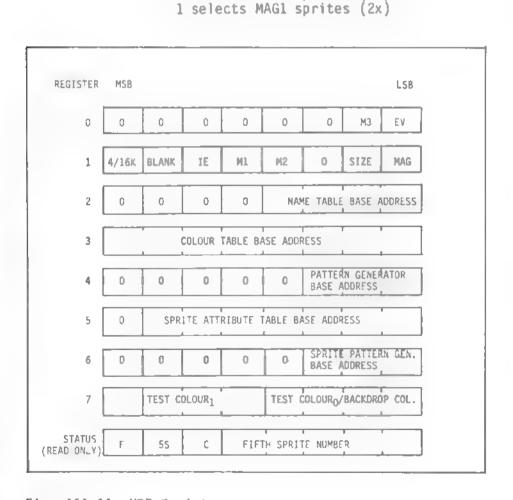

Fig. III-11. VDP Registers

3-2-2-3. Register 2

Register 2 defines the base address of the Name Table sub-block. The range of its contents is from 0 to 15. The contents of the register form the upper 4 bits of the 14-bit Name Table addresses; thus the Name Table base address is equal to (Register 2) *400 (hex).

3-2-2-4. Register 3

Register 3 defines the base address of the Colour Table sub-block. The range of its contents is from 0 to 255. The contents of the register form the upper 89 bits of the 14-bit Colour Table addresses, thus the Colour Table base address is equal to (Register 3) *40 (hex).

3-2-2-5. Register 4

Register 4 defines the base address of the Pattern, text of Multicolour Generator sub-lock. The range of its contents is 0 through 7. The contents of the register form the upper 3 bits of the 14-bit Generator addresses, thus the Generator base address is equal to (Register 4) *800 (hex).

3-2-2-6. Register 5

Register 5 defines the base address of the Sprite Attribute Table sub-lock. The range of its contents is from 0 through 127. The contents of the register form the upper 7 bits of the 14-bit Sprite Attribute Table addresses; thus the base address is equal to (Register 5) *80 (hex).

3-2-2-7-. Register 6

Register 6 defines the base address of the Sprite Pattern Generator sub-lock. The range of its contents is 0 through 7. The contents of the register form the upper 3 bits of the 14-bit Sprite Pattern Generator address; thus the Sprite Pattern Generator base address is equal to (Register 6) *800 (hex).

3-2-2-8. Register 7

The upper 4 bits of Register 7 contain the colour code of colour 1 in the Text mode. The lower 4 bits contain the Colour mode for colour 0 in the Text mode and the backdrop colour in all modes.

3-2-2-9. Setup Values for VDP Registers 2 through 6.

VRAM TABLE ADDRESSING

3-2-3. Status Register

The VDP has a single 8-bit status register that can be accessed by the CPU. The status register contains the interrupt pending flag, the sprite coincidence flag, the fifth sprite flag and the fifth sprite number, if one exists. The format of the status register is shown in Figure III-11 and is discussed in the following paragraphs.

The status register may be read at any time to test the F, C, and 5S status bits. Reading the status register will clear the interrupt flag F. However, asychronous reads will cause the frame flag (F) bit to be reset and therefore missed. Consequently, the status register should be read only when the VDP interrupt is pending.

3-2-3-1. Interrupt Flag (F)

The F status flag in the status register is set to 1 at the end of the raster scan of the last line of the active display. It is reset to a 0 after the status register is read or when the VDP is externally reset. If the Interrupt Enable bit in VDP Register 1 is active (1), the VDP interrupt output (INT) will be active (low) whenever the F status is a 1.

Note that the status register needs to be read frame by frame in order to clear the interrupt and receive the new interrupt of the next frame.

3-2-3-2. Coincidence Flag (C)

The C status flag in the status register is set to a 1 if two or more sprites coincide. Coincidence occurs if any two sprites on the screen have one overlapping pixel. Transparent coloured sprites, as well as those that are partially or completely off the screen, are also considered. Sprites beyond the Sprite Attribute Table terminator (DO16) are not considered.

The C flag is cleared to a O after the status register is read or the VDP is externally reset. The status should be read immediately upon power up to ensure that the coincidence flag is reset.

The VDP checks each pixel position for coincidence during the generation of the pixel regardless of where it is located on the screen. This occurs every 1/60th of a second for the TMS9918A and TMS9928A and every 1/50th of a second for the TMS9929A. Thus, when moving sprites more than one pixel position during these intervals, it is possible for the sprites to have multiple pixels overlapping or even to have passed completely over one another when the VDP checks for coincidence.

3-2-3-3. Fifth Sprite Flag (5S) and Number

The 5S status flag in the status register is set to a 1 whenever there are five or more sprites on a horizontal line (lines 0 to 192) and the frame flag is equal to a 0. The 5S status flag is cleared to a 0 after the status register when the 5S flag is set and is valid whenever the 5S flag is one. The setting of the fifth sprite flag will not cause an interrupt.

3-2-4. Video Display Modes

The VDP displays an image on the screen that can best be envisioned as a set of display planes sandwiched together. Figure III-12 shows the definition of each of the planes. Objects on planes closest to the viewer have higher priority. In cases where two entities on two different planes are occupying the same spot on the screen, the entity on the higher priority plane will show at that point. For an entity on 2 specific plane to show through, all planes in front of that plane must be outside of the sprite itself, are transparent. Since the coordinates of the sprite are in terms of pixels, the sprite can be positioned and moved about very accurately. Sprites are available in three sizes 8 x 8 pixels, 16 x 16 pixels, and 32 x 32 pixels.

Behind the Sprite Planes is the Pattern Plane. The Pattern Plane is used for textual and graphics images generated by the Text, Graphics I, Graphics II, or Multicolour modes. Behind the Pattern Plane is the backdrop, which is larger in area than the other planes so that it forms a border around the other planes. The last and lowest priority plane is the External VDP Plane. Its image is defined by the external VDP input pin which allows the TMS9918A to mix the external video signal internal to the chip.

The mixing must occur outside of the chip for the TMS9928A and TMS9929A. This is achieved through the colour difference outputs swinging to a special level (sync level is shown in fig. III-14) not used by the colour difference signals in normal operation. This occurs when bit 7 of Register 0 is set high. External mixing circuitry is required to detect this change in the level of the colour difference signals and then switch from the VDP signals to an external source's signals (see figure III-15 and III-16).

4. The 8910 PSG

4-1. Introduction

It is apparent that any microprocessor is capable of producing acceptable sounds with only a transducer if the processor has no other tasks to perform while the sound is sustained. In real world microprocessor use, however, video games need refreshing, keyboards need scanning, etc. For example, in order to produce a single channel of ninth octave C (8372 Hz) the signal needs attention every sixty microseconds. Software required to produce this simple effect and still perform other activities would in the least be very complex if not impossible. In the extreme, random noise requires periodic attention even more frequently.

This need for software-produced sounds without the constant attention of the processor is now satisfied with the availability of the General Instrument AY-3-8910 and AY-3-8912 Programmable Sound Generators.

4-1-1. Description

The AY-3-8910/8912 Programmable Sound Generator (PSG) is a Large Scale Integrated Circuit which can produce a wide variety of complex sounds under software control. The AY-3-8910/8912 is manufactured in GI's N-channel Ion Implant Process. Operation requires a single 5V power supply, a TTL compatible clock, and a microprocessor controller such as the GI-16-bit CP1600/1610 or one of GI's PIC1650 series of 8-bit microcomputers.

The PSG is easily interfaced to any bus oriented system. Its flexibility makes it useful in applications such as music synthesis, sound effects generation, audible alarms, tone signalling and FSK modems. The analog sound outputs can each provide 4 bits of logarithmic digital to analog conversion, greatly enhancing the dynamic range of the sounds produced.

In order to perform sound effects while allowing the processor to continue its other tasks, the PSG can continue to produce sound after the initial commands have been given by the control processor. The fact that realistic sound production often involves more than one effect is satisfied by the three independently controllable channels available in the PSG.

All of the circuit control signals are digital in nature and intended to be provided directly by a microprocessor/microcomputer. This means that one PSG can produce the full range of required sounds with no change in external circuitry. Since the frequency response of the PSG ranges from sub-audible at its lowest frequency to post-audible at its highest frequency, there are few sounds which are beyond reproduction with only the simplest electrical connections.

Since most applications of a microprocessor/PSG system would also require interfacing between the outside world and the microprocessor, this facility has been designed into the PSG. The AY-3-8910 has two general purpose 8-bit I/O ports and is supplied in a 409 lead package; in the AY-3-8912 has one port and 28 leads.

4-1-2. Features

- Full software control of sound generation.
- Interface to most 8-bit and 16-bit microprocessors
- Three independently programmed analog outputs.
- Two 8-bit general purpose I/O ports (AY-3-8910)
- One 8-bit general purpose I/O port (AZ-3-8912)
- Single +5 Volt Supply.

4-1-3. Scope

This Data Manual is intended to introduce the techniques needed to cause the AY-3-8910/8912 Programmable Sound Generator to perform in its intended fashion. All of the programs, programming, and hardware designs have been tested to ensure that the methods are practical rather than purely theoretical.

Although the techniques described will produce powerful results, the range of sounds to be synthesized is so vast and the PSG capabilities so varied that this guide should be viewed merely as an introduction to the applications possiblities of the PSG.

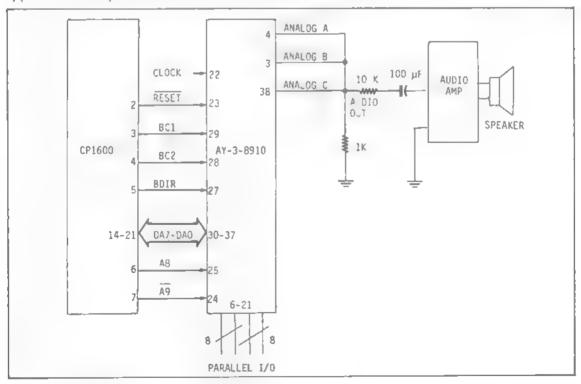

Fig. III-17. Typical System Diagram

4-2. Architecture

The AY-3-8910/8912 is a register oriented Programmable Sound Generator (PSG). Communication between the processor and the PSG is based on the concept of memory-mapped I/O. Control commands are issued to the PSG by writing to 16 memory-mapped register. Each of the 16 registers within the PSG is also readable so that the microprocessor can determine as necessary present states or stored data values.

All functions of the PSG are controlled through its 16 registers which once programmed, generate and sustain the sounds, thus freeing the system processor for other tasks.

4-2-1. Basic Functional Blocks

The principal element of the PSG is the array of 16 read/write control registers. These 16 registers look to the CPU as a block of memory and as such occupy a 16 word block out of 1.024 possible addresses. The 10 address bits (8 bits on the common data/address bus and 2 separate address bits A8 and A9) are decoded as follows

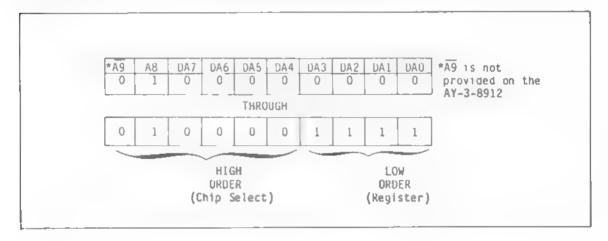

Fig. III-18.

The four low order address bits select one of the 16 registers (RO--R17g). The six high order address bits function as "chip selects" to control the tri-state bidirectional buffers (when the high order address bits are "incorrect", the bidirectional buffers are forced to a high impedance state). High order address bits A9 A8 are fixed in the PSG design to recognize a O1 code; high order address bits DA7--DA4 may be mask-programmed to any 4-bit code by a special order factory maks modification. Unless otherwise specified, address bits DA7-DA4 are programmed to recognize only a O000 code. A valid high order address latches the register address (the low order 4 bits) in the Register Address Latch/Decoder block. A latched address will remain valid until the receipt of a new address, enabling multiple reads and writes of the same register contents without the need for redundant re-addressing.

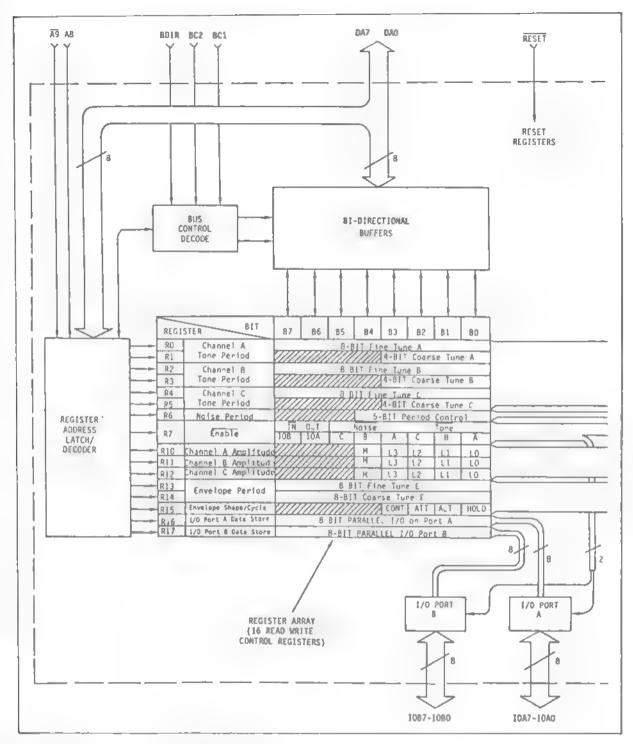

Fig. III-19 a. PSG Block Diagram

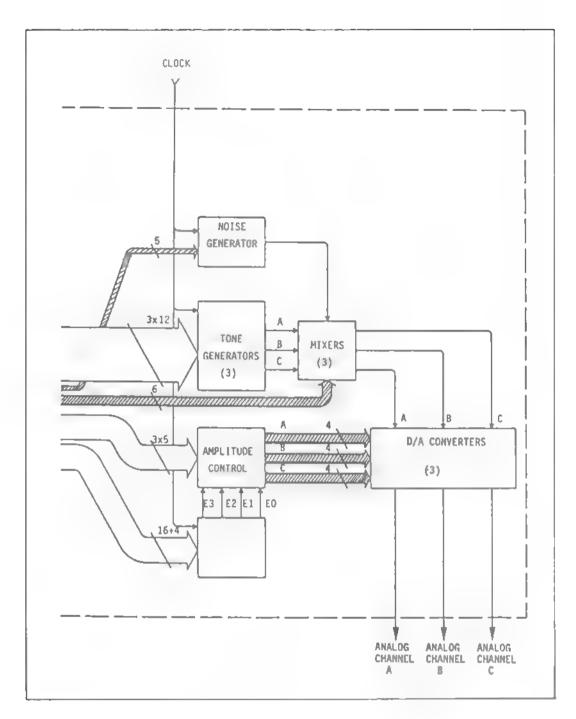

Fig. III-19 b.

Conditioning of the Register Address Latch/Decoder and the Bidirectional Buffers to recognize the bus function required (inactive, latch address, write data, or read data) is accomplished by the Bus Control Decode block.

The function of each of the 16 PSG registers and the data flow of each register's contents are shown in contents in Fig. III-17 and explained in detail in Section 4-3, "Operation". For reference purposes, the Register Array details are reproduced in Fig. III-19 a & b.

4-2-1-2. Sound Generating Blocks

The basic blocks in the PSG which produce the programmed sounds include:

Tone Generators produce the basic square wave tone frequencies for each channel (A. B. C)

Noise Generator produces a frequency modulated pseudo random pulse width square wave output.

Mixers combine the outputs of the Tone Generators and the Noise Generator. One for each channel (A, B, C).

Amplitude Control provides the D/A Converters with either a fixed or variable amplitude pattern. The fixed amplitude is under direct CPU control; the variable amplitude is accomplished by using the output of the Envelope Generator.

Envelope Generator produces an envelope pattern which can be used to amplitude modulate the output of each Mixer.

D/A Converters the three D/A Converters each produce up to a 16 level output signal as determined by the Amplitude Control.

4-2-1-3. I/O Ports

Two additional blocks are shown in the PSG Block Diagram which have nothing directly to do with the production of sound - these are the two I/O Ports (A and B). Since virtually all uses of microprocessor-based sound would require interfacing between the outside world and the processor, this facility has been included in the PSG. Data to/from the CPU bus may be read/written to either of two 8-bit I/O Ports without affecting any other function of the PSG. The I/O Ports are TTL-compatible and are provided with internal pull-ups on each pin. Both Ports are available on the AY-3-8910; only I/O Port A is available on the AY-3-8912.

Table III-11. PSG Register Array

4-2-3. Pin Function

DA7 - DA0 (input/output/high impedance): pins 30 -- 37 (AY-3-8910) Data/Address 7 - 0: pins 21 -- 28 (AY-3-8912)

These 8 lines comprise the 8-bit bidirectional bus used by the microprocessor to send both data and addresses to the PSG and to receive data from the PSG. In the data mode, DA7 -- DAO correspond to Register Array bits B7 -- DAO in conjunction with address inputs A9 and A8 form the high order address (chip select).

A8 (input): pin 25 (AY-3-8910) pin 17 (AY-3-8912)

A9 (input): pin 24 (AY-3-8910) (not provided on AY-3-8912)

Address 9, Address 8

These "extra" address bits are made available to enable the positioning of the PSG (assigning a 16 word memory space) in a total 1.024 word memory area rather than in a 256 word memory areas as defined by address bits DA7 - DAO alone. If the memory size does not require the use of these extra address lines they may be left unconnected as each is provided with either an on-chip pull-down (A9) or pull-up (A8) resistor. In "noisy" environments, however it is recommended that A9 and A8 be tied to an external ground and +5V, respectively, if they are not to be used.

RESET (input): pin 23 (AY-3-8910) pin 16 (AY-3-8912) For initialization/power-on purposes, applying a logic "O" (ground) to the Reset pin will reset all registers to "O". The Reset pin is provided with an on-chip pull-up resistor.

CLOCK (input): pin 22 (AY-3-8910) pin 15 (AY-3-8912)

This TTL-compatible input supplies the timing reference for the Tone, Noise and Envelope Generators.

BDIR, BC2, BC1 (inputs): pins 27, 28, 29 (AY-3-8910) pins 18, 19, 20 (AY-3-8912)

Bus DIRection, Bus Control 2, 1

These bus control signals are generated directly by GI's CP1600 series of microprocessors to control all external and internal bus operations in the PSG. When using a processor other than the CP1600, these signals can be provided either by comparable bus signals or by simulating the signals on I/O lines of the processor. The PSG decodes these signals as illustrated in the following:

BDIR	BC2	BC1	CP1600 FUNCTION	PSG FUNCTION
0	0	0	NACT	INACTIVE, See 010 (TAB) below.
0	0	1	ADAR	LATCH ADDRESS See 111 (INTAK) below
0	1	0	IAB	INACTIVE The PSG/CPU bus is inactive DA7-DAO are in a high impedance state.
0	1	1	DTB	READ FROM PSG. This signal causes the contents of the register which is currently addressed to appear on the PSG/CPU bus. DA7-DAO are in the input mode.
1	0	0	BAR	LATCH ADDRESS. See 111 (INTAK) below.
1	0	1	DW	INACTIVE. See 010 (IAB) above.
1	1	0	DWS	WRITE TO PSG. This signal indicates that the bus contains register data which should be latched into the currently addressed register. DA7DA0 are in the input mode.
1	1	1	INTAK	LATCH ADDRESS. This signal indicates that the bus contains a register address which should be latched in the PSG. DA7 - DAO are in the input mode.

While interfacing to a processor other than the CP1600 would simply require simulating the above decoding, the redundancies in the PSG functions vs. bus control signals can be used to advantage in that only four of the eight possible decoded bus functions are required by the PSG. This could simplify the programming of the bus control signals to the following, which would only require that the processor generate two bus control signals (BDIR and BC1, with BC2 tied to +5V) See fig. III-17.

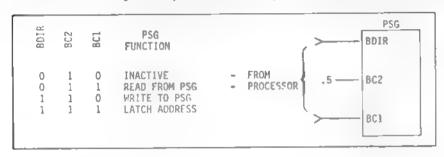

Fig. III-20.

Each of these signals is the output of its corresponding D/A Converter, and provides an up to 1V peak-peak signal representing the complex sound waveshape dererated by the PSG.

Input/Output A7 -- A0, B7 -- B0

Each of these two parallel input/output ports provides 8 bits of parallel data to/from the PSG/CPU bus from/to any external devices connected to the IOA or IOB pins. Each pin is provided with an on-chip pull-up resistor, so that when in the 'input' mode, all pins will read normally high. Therefore, the recommended method for scanning external switches, for example, would be to ground the input bit.

These pins are for GI test purposes only and should be left open - do not use as tie-points.

Nominal +5Volt power supply to the PSG.

V_{ss}: pin 1 (AY-3-8910) pin 6 (AY-3-8912) Ground reference for the PSG.

4-3. Operation

Since all functions of the PSG are controlled by the host processor via a series of register loads, a detailed description of the PSG operation can best be accomplished by relating each PSG function to the control of its corresponding register. The function of creating or programming a specific sound or sound effect logically follows the control sequence listed:

Section	Operation	Register	Function
4-3-1.	Tone Generator Control	R0-R5	Program tone periods.
4-3-2.	Noise Generator Control	R6	Program noise period.
4-3-3.	Mixer Control	R7	Enable tone and/or noise on selected channels.
4-3-4.	Amplitude Control	R10-R12	Select "fixed" or "envelope-variable" amplitudes.
4-3-5.	Envelope Generator Control	R13R15	Program envelope period and select envelope pattern.

4-3-1. Tone Generator Control

The frequency of each square wave generated by the three Tone Generators (one each for Channels A, B, and C) is obtained in the PSG by first counting down the input clock by 16, then by further counting down the result by the programmed 12-bit Tone Period value. Each 12-bit value is obtained in the PSG by combining the contents of the relative Coarse and Fine Tune registers, as illustrated in the following.

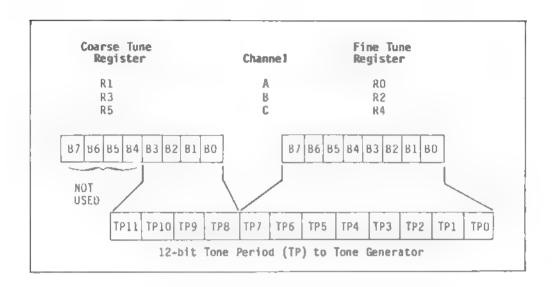

Fig. III-21.

Note that the 12-bit value programmed in the combined Coarse and Fine Tune registers is a period value - the higher the value in the registers, the lower the resultant tone frequency.

Note also that due to the design technique used in the Tone Period count-down, the lowest period, value is 000000000001 (divide by 1) and the highest period value is 11111111111 (divide by 4.095 $_{10}$)

The equations describing the relationship between the desired output tone frequency and the input clock frequency and Tone Period value are:

(a)
$$f_T = \frac{f_{CLOCK}}{16TP_{10}}$$
 (b) $TP_{10} = 256CT_{10} + FT_{10}$

Where: F_T = desired tone frequency

f_{CLOCK} = input clock frequency

 TP_{10} = decimal equivalent of the Tone Period bits TP11-TP0

 CT_{10} = decimal equivalent of the Coarse Tune register bits B3-B0 (TP11--TP8)

 FT_{10} = decimal equivalent of the Fine Tune register bits B7--B0 (TP7--TP0)

From the above equations it can be seen that the tone frequency can range from a low of $\frac{f_{CLOCK}}{65.520}$ (wherein: $TP_{10} = 4.095_{10}$) to a high of $\frac{f_{CLOCK}}{16}$ (wherein: $TP_{10} = 1$). Using a 2MHz input clock, for example, would

produce a range of tone frequencies from 30.5Hz to 125kHz. To calculate the values for the contents of the Tone Period Coarse and Fine Tune registers, given the input clock and the desired output tone frequencies, we simply rearrange the above equations, yielding:

(a)
$$TP_{10} = \frac{f_{CLOCK}}{16f_T}$$
 (b) $CT_{10} + \frac{FT_{10}}{256} = \frac{TP_{10}}{256}$

Example 1:
$$f_{\uparrow} = 1 \text{KHz}$$

$$TP_{10} = \frac{2 \times 10^6}{16(1 \times 10^3)} = 125$$

Substituting this result into equation (b):

$$CT_{10}$$
 + $\frac{FT_{10}}{256} = \frac{125}{256}$
.*. $CT_{10} = 0$ = 0000 (B3--B0)
 $FT_{10} = 125_{10}$ = 0111101 (B7--B0)

Example 2:
$$f_T = 100 \text{ Hz}$$

$$f_{CLOCK} = 2 \text{MHz}$$

$$TP_{10} = \frac{2 \times 10^6}{16(1 \times 10^2)} = 1250$$

Substituting this result into equation (b):

$$CT_{10} + \frac{FT_{10}}{256} = \frac{1250}{256} = 4 + \frac{226}{256}$$

$$. CT_{10} = 4_{10} = 0100 \text{ (B3--B0)}$$

$$FT_{10} = 226_{10} = 11100010 \text{ (B7--B0)}$$

The frequency of the noise source is obtained in the PSG by first counting down the input clock by 16, then by further counting down the result by the programmed 5-bit Noise Period value. This 5-bit value consists of the lower 5 bits (84--80) of register R6, as illustrated in the following.

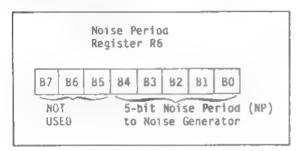

Fig. 111-22.

Note that the 5-bit value in R11 is a period value - the higher the value in the register, the lower the resultant noise frequency. Note also that, as with the Tone Period, the lowest period value is 00001 (divide by 1): the highest period value is 11111 (divide by 31_{10}).

The noise frequency equation is:

$$\begin{split} f_N &= \frac{f_{CLOCK}}{16\text{NP}_{10}} \\ \text{where:} \quad f_N &= \text{desired noise frequency} \\ f_{CLOCK} &= \text{input clock frequency} \\ \text{NP}_{10} &= \text{decimal equivalent of the Noise Period register bits } 84--80 \end{split}$$

From the above equation it can be seen that the noise frequency can range from a low of $\frac{f_{\text{CLOCK}}}{496}$ (wherein: NP₁₀ = 31₁₀) to a high of $\frac{f_{\text{CLOCK}}}{16}$ (wherein: NP₁₀=1). Using a 2MHz input clock, for example, would produce a range of noise frequencies from 4kHz to 125kHz.

To calculate the value for the contents of the Noise Period register, given the input clock and the desired output noise frequencies, we simply rearrange the above equation, yielding:

$$NP_{10} = \frac{f_{CLOCK}}{16f_N}$$

Register 7, is a multi-function Enable register which controls the three Noise/Tone Mixers and the two general purpose I/O Ports.

The Mixers, as previously described, combine the noise and tone frequencies for each of the three channels. The determination of combining neither/either/both noise and tone frequencies on each channel is made by the state of bits B5--BO of R7.

The direction (input or output) of the two general purpose I/O Ports (IOA and IOB) is determined by the state of bits B7 and B6 of R7.

These functions are illustrated in the following:

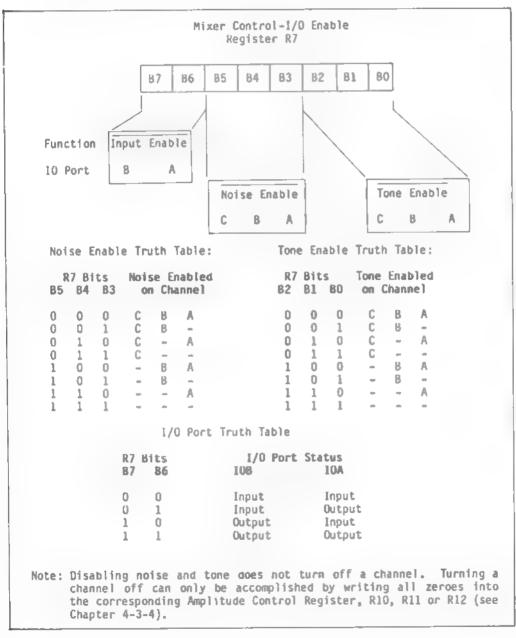

Fig. III-23.

The amplitudes of the signals generated by each of the three D/A Converters (one each for Channel A, B and C) are determined by the contents of the lower 5 bits (B4--B0) of registers R10, R11 and R12 as illustrated in the following:

Amplitude Control Register A	Channe1
R10 R11 R12	A B C
B7 B6 B5 B4 B3	B2 81 B0
NOT USED M	L3 L2 L1 L0
	4-bit fixed plitude level

Fig. III-24.

The amplitude "mode" (bit M) selects either fixed level amplitude (M=0) or variable level amplitude (M=1). It follows then that bits L3--L0, defining the value of a "fixed" level amplitude, are only active when M=0. When fixed level amplitude is selected, it is "fixed" only in the sense that the amplitude level is under the direct control of the system processor (via bits D3--D0). Varying the amplitude when in this "fixed" amplitude mode requires in each instance the direct intervention of the system processor via an address latch/write data sequence to modify the D3--D0 data.

When M=l (select "variable" level amplitudes), the amplitude of each channel is determined by the envelope pattern as defined by the Envelope Generator's 4-bit output E3 E2 E1 E0.

The amplitude "mode" (bit M) can also be thought of as an "envelope enable" bit, i.e. when M = 0 the envelope is not used, and when M = 1 the envelope is enabled. (A full description of the Envelope Generator function follows in Section 4-3-5).

The full chart describing all combinations of the 5-bit Amplitude Control is as follows:

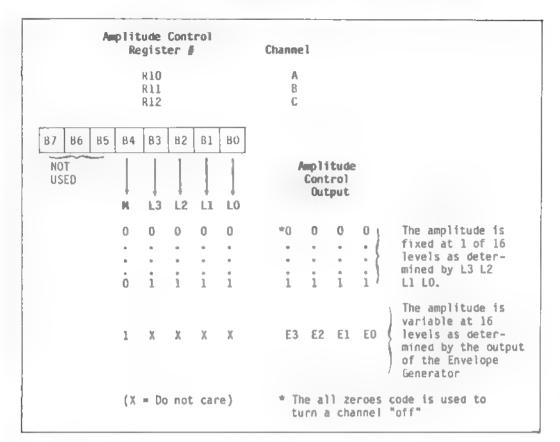

Fig. III-25.

Fig. III-26. graphically illustrates a selection of variable level (envelope-controlled) amplitude where the 16 levels directly reflect the output of the Envelope Generator. A fixed level amplitude would correspond to only one of the levels shown, with the level directly determined by the decimal equivalent of bits L3 L2 L1 L0.

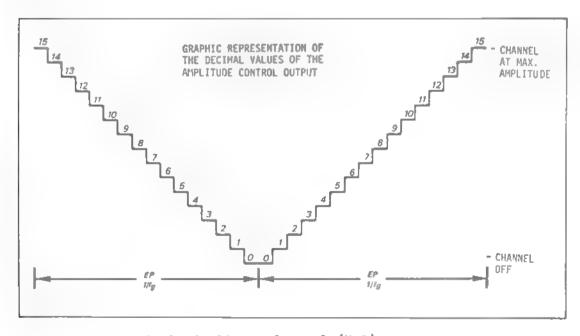

Fig. III-26. Variable Amplitude Control (M=1)

To accomplish the generation of fairly complex envelope patterns, two independent methods of control are provided in the PSG: first, it is possible to vary the frequency of the envelope using registers R13 and R14; and second, the relative shape and cycle pattern of the envelope can be varied using register R15. The following paragraphs explain the details of the envelope control functions, describing first the envelope period control and then the envelope shape/cycle control.

4-3-5-1. Envelope Period Control (Registers R13, R14)

The frequency of the envelope is obtained in the PSG by first counting down the input clock by 256, then by further counting down the result by the programmed 16-bit Envelope Period value. This 16-bit value is obtained in the PSG by combining the contents of the Envelope Coarse and Fine Tune registers, all illustrated in the following:

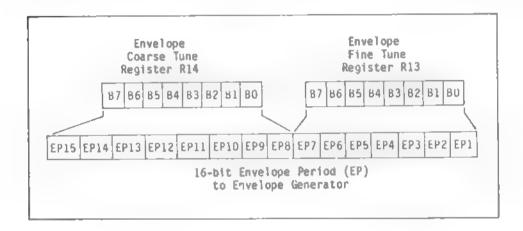

Fig. III-27.

Note that the 16-bit value programmed in the combined Coarse and Fine Tune registers is a period value - the higher the value in the registers, the lower the resultant envelope frequency.

The envelope frequency equations are:

(a)
$$F_E = \frac{f_{CLOCK}}{256EP_{10}}$$
 (b) $EP_{10} = 256CT_{10} + FT_{10}$

Where: $f_E = desired envelope frequency$

 f_{CLOCK} = input clock frequency

 ${\sf EP}_{10}$ =decimal equivalent of the Envelope Period bits ${\sf EP15--EP0}$

CT₁₀ =decimal equivalent of the Coarse Tune register
 bits B7--B0 (EP15--EP8)

 FT_{10} = decimal equivalent of the Fine Tune register bits 87--B0 (EP7--EP0)

From the above equation it can be seen that the envelope frequency can range from a low of $\frac{{}^f\text{CLOCK}}{16.7/6.960}_{10} \text{ (wherein: EP}_{10} = 65.535_{10}\text{)}$ to a high of $\frac{{}^f\text{CLOCK}}{256} \text{ (wherein: EP}_{10}=1\text{)}.$

Using a 2MHz clock, for example, would produce a range of envelope frequencies from 0.12Hz to 7812.5Hz.

To calculate the values for the contents of the Envelope Period Coarse and Fine Tune registers, given the input clock and the desired envelope frequencies, we rearrange the above equations, yielding

(a)
$$EP_{10} = \frac{f_{CLOCK}}{256f_E}$$
 (b) $CT_{10} + \frac{FT_{10}}{256} = \frac{EP_{10}}{256}$

Example:
$$f_E = 0.5Hz$$

$$f_{CLOCK} = 2MHz$$

$$EP_{10} = \frac{2 \times 10^6}{256(0.5)} = 15.625$$

Substituting this result into equation (b):

$$CT_{10} + \frac{FT_{10}}{256} = \frac{15.625}{256} = 61 + \frac{9}{256}$$

$$CT_{10} = 61_{10} = 00111101 (B7--B0)$$

$$FT_{10} = 9_{10} = 00001001 (B7--B0)$$

4-3-5-2. Envelope Shape/cycle control (Register R15)

The Envelope Generator further counts down the envelope frequency by 16, producing a 16-state per cycle envelope pattern as defined by its 4-bit counter output, E3 E2 E1 E0. The particular shape and cycle pattern of any desired envelope is accomplished by controlling the count pattern (count up/count down) of the 4-bit counter and by defining a single-cycle or repeat-cycle pattern.

This envelope shape/cycle control is contained in the lower 4 bits (B3--B0) of register R15. Each of these 4 bits controls a function in the envelope generator, as illustrated in the following.

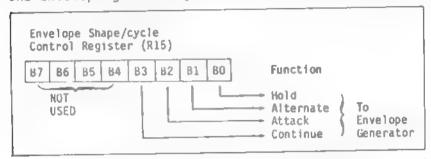

Fig. III-28. The definition of each function is as follows:

when set to logic "1", limits the envelope to one cycle, holding the last count of the envelope counter (E3--E0 = 0000 or 1111, depending on whether the envelope counter was in a count-down or count-up mode, repectively).

Alternate when set to logic "l", the envelope counter reverses count direction (up-down) after each cycle.

NOTE: When both the Hold bit and the Alternate bit are ones, the envelope counter is reset to its initial count before holding.

Attack when set to logic "1", the envelope counter will count up (attack) from E3 E2 E1 E0 = 0000 to E3 E2 E1 E0 = 1111; when set to logic "0", the envelope counter will count down (decay) from 1111 to 0000.

Continue when set to logic "1", the cycle pattern will be as defined by the hold bit; when set to logic "0" the envelope generator will reset to 0000 after one cycle and hold at that count.

To further describe the above functions could be accomplished by numerous charts of the binary count sequency of E3 E2 E1 E0 for each combination of Hold, Alternate, Attack and Continue. However, since these outputs are used (when selected by the Amplitude Control registers) to amplitude modulate the output of the Mixers, a better understanding of their effect can be accomplished via a graphic representation of their value for each condition selected, as illustrated in Fig. III-29 and III-30.

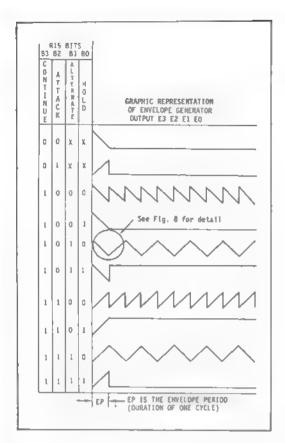

Fig. III-29. Envelope Shape/Cycle Control

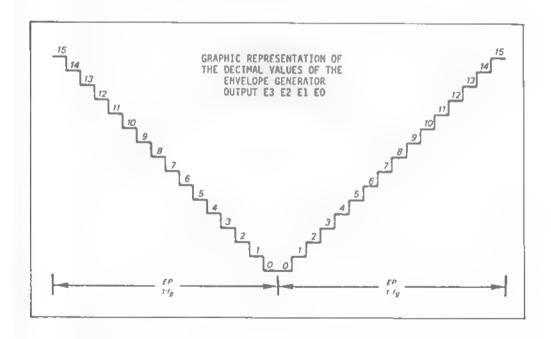

Fig. III-30. Detail of two Cycles of Fig. III-29.

4-3-6. I/O Port Data Store (Register R16, R17)

Registers R16 and R17 function as intermediate data storage registers between the PSG/CPU data bus (DAO--DA7) and the two I/O ports (10A7--10A0) and 10B7--10B0). Both ports are available in the AY-3-8910, only I/O Port A is available in the AY-3-8912. Using registers R16 and R17 for the transfer of I/O data has no effect at all on sound generation.

To output data from the CPU bus to a peripheral device connected to ${\rm I/O}$ Port A would require only the following steps:

- 1. Latch address R7 (select Enable register)
- Write data to PSG (setting B6 of R7 to "1")
 Latch address R16 (select IOA register)
- 4. Write data to PSG (data to be output on I/O Port A)

To input data from I/O Port A to the CPU bus would require the following:

- Latch address R7 (select Enable register)
 Write data to PSG (setting B6 to R7 to "0")
- 3. Latch address R16 (select IOA register)
- 4. Read data from PSG (data from I/O Port A)

Note that once loaded with data in the output mode, the data will remain on the I/O port(s) until changed either by loading different data by applying a reset (grounding the Reset pin), or by switching to the input mode.

Note also that when in the input mode, the contents of registers R16 and/or R17 will follow the signals applied to the I/O port(s). However, transfer of this data to the CPU bus requires a "read" operation as decribed above.

PART IV

MSX-DOS

1. Introduction

The Microsoft Extended Disk Operating System (MSX-DOS) emulates the CP/M80 function calls (the 8-bit Digital Research's CP/M system) but contains the MS-DOS file formats (the 16-bit Microsoft's MS-DOS system). This part is intended to supply the technically oriented users with information about the structure, facilities and program interfaces of MSX-DOS.

It is assumed that the reader is familiar with the Z-80 architecture and instruction set.

This information will help programmers when running CP/M-80 software in a MSX-DOS environment.

2. The MSX-DOS Structure

The MSX-DOS consists of the following parts:

- A Cold Boot record, residing on track Ø, sector 1 of every disk formatted by the FORMAT command. It is put on all disks in order to produce an error message if you try to start up the system with a non-MSX-DOS diskette in drive A:.
- A ROM based BIOS interface module. This Basic Input Output System (BIOS) links the hardware environment to the standard MSX-DOS kernel.
- The ROM based MSX-DOS kernel, providing a high-level interface for user programs.
- 4. The command processor (COMMAND, COM) which resides on the data area of the disk.

3. The MSX-DOS Disk Organization

- The Sony 3.5" Floppy Disk (Single Sided, Double Density) is organized by the FORMAT command as follows:
 - 80 Tracks/side (0 79)
 - 9 sectors/track (1 9)

- 512 bytes/sector

The formatted storage capacity = 360 Kilobytes.

- The cold boot loader resides on track Ø, sector 1 as mentioned in the MSX-DOS Structure.
- 3. The 1st File Allocation Table (FAT #0) resides on track Ø, sectors 2 and 3.
 A 2nd FAT (FAT #1) resides on track Ø, sectors 4 and 5.
 There are two FAT's for redundancy reasons.
 They are normally identical except when they are being updated or if they have been corrupted in some fashion.
 Only one copy of these FAT's is kept in memory by MSX-DOS for each disk, and both copies on the disk are updated one after the other as required.
- 4. The remaining 4 sectors of track Ø (sectors 6, 7, 8 and 9) and the first 3 sectors of track 1 (sectors 1, 2 and 3) are used for the disk DIRECTORY.
 As each directory entry is 32 bytes in length, 112 directory entries can be made on a disk. The format of such an entry is as follows (byte offsets are in decimal).
 - 0 7 Filename (8 bytes)
 The first byte of this field indicates the status of this entry:

8yte 0 Description
00 hex entry never used
E5 hex entry erased
other first character of the filename.

8 - 10 File type (3 bytes)

24 - 25 Date field (creation or last update)
 The month/day/year information is mapped in the bits as follows:

where D D D D D = day (1 - 31)M M M M = month (1 - 12)Y Y Y Y Y = year (0 - 119)

Note that the year number is an offset from year 1980

- 26 27 Starting cluster: the relative cluster number of the first cluster in the file. Note that the first cluster for the data area is always cluster #002. This number is stored with the least significant byte first.
- 28 31 file size in bytes. The first word (28 29) contains the low-order part of the size. Both words are stored with the least significant byte first.

5. The remaining sectors on track 2 (sector 4, 5, 6, 7, 8 and 9) and all the sectors of the other tracks are used for the DATA area.

4. MSX-DOS File Allocation

MSX-DOS uses "clusters" for storing data on a disk. Essentially, a cluster is a fixed-size block of disk sectors. Disk space is allocated in "clusters" and not in sectors.

For the SONY 3.5" F.D. following data are used:

- 354 clusters/disk in total.

- 351 clusters/disk for data storage.

- 2 sectors/cluster

As the sector size is 512 bytes, a cluster equals 1 KByte. This implies that a program of 200 bytes will actually use 1 cluster or 1Kbyte of disk space. A file of 1025 bytes (1KByte + 1) will need 2 clusters or 2 KByte of disk space.

The allocation of the clusters is stored in the FAT area of the disk. Each FAT entry (12 bits or 1.5 byte) corresponds to one "cluster" in the DATA area.

The FAT index in the DIRECTORY entry of a file indexes the first FAT entry for the file. This entry contains an index for the next FAT entry for the file and so on.

Any data record in a file can be found by computing the cluster index containing the data and searching the file's allocation chain in the FAT to find the appropriate cluster.

5. MSX-DOS Function Requests

The user requests a function by:

1. Placing a function number in the C register.

Supplying additional information in other registers for the specific function.

3. Executing a CALL DODSH instruction.

Unless otherwise specified, single-byte values are passed in E and double-byte values in DE. When MSX-DOS takes control, it switches to an internal stack. No registers are guaranteed to be preserved, MSX-DOS returns single-byte values in register A and double-byte values in register pair HL. In addition, the contents of register A will always equal those of register L, and the contents of B will equal H for those calls which have a CP/M-80 counterpart. A value of zero will be returned in A (as well as HL) for non-supported function numbers.

Function numbers are as follows. All values are in hex:

- O Program Terminate: All file buffers are flushed, but files which have been changed in length (but not closed) will not be recorded properly in the disk directory. Control transfers back to MSX-DOS. This is the same as JMP DDDDH.
- 1 Keyboard: Waits for a character to be typed at the keyboard, then echoes the character to the screen and returns it in A. A console status check is done to check to Control-C, printer echo, and Control-S. These characters will not be passed through this call. Execution will be suspended until a character is typed, if none was waiting when the call was made. Carriage Return, Line Feed, Backspace, and Bell are echoed as such. Tabs are expanded.
- 2 Screen Output: The character in E is output to the screen in a fashion similar to function 1. A console status check is performed after the character is output. A VT52 driver is built into the BIOS.

Microsoft MSX-DOS

Escape sequences are:

J E	Clear screen
	Clear screen
K	Erase to end of line
J	Erase to end of screen
1	(Lowercase L) Erase entire line
L	Insert a line
M	Delete a line
Υ	Locate cursor
A	Up
В	Down
C	Right
D	Left
H	Home
x4	Block cursor
у4	Underscore cursor
x5	Cursor off
y5	Cursor on

- 3 Auxiliary Input: Waits for a character from the serial port and returns it in A. A console status check is done beforehand, suspending reading from this device if Control-S is detected.
- 4 Auxiliary Output: The character in E is sent to the serial port. A console status check is performed beforehand.
- 5 Printer Output: The character in E is output to the printer. As console status check is performed beforehand. Tabs are not expanded by the DOS.

- Direct Console IO: If E is FFH, then A returns with keyboard input character if one is ready and zero flag is not set; otherwise, AZ is zero and zero flag is set. If E is not FFH, the E is assumed to have a valid character which is output to the screen. A console status check is not performed, passing through the values Control-C and Control-S.
- 7 Direct Console Input: Waits for a character to be typed at the keyboard, then returns the character in A. As with Function 6, no console status check is performed.

Note that CP/M-80 Function 7 is Set I/O Byte. I/O byte is not supported under MSX-DOS.

8 Keyboard Input without Echo: Identical to Function 1, without displaying the character.

Note that CP/M-80 Function 8 is Set I/O Byte. I/O byte is not supported under MSX-DOS.

- Display String: On entry DE must point to a character string in memory terminated with a "\$" (24H). Each character in the string will be displayed to the screen in the same form as Function 2, including console status check.
- A Buffered Keyboard Input: On entry, DE points to an input buffer. The first byte must not be zero and specifies the number of characters the buffer can hold. Characters are read from the keyboard and placed in the buffer at the third byte. Reading the keyboard and filling the buffer continues until the carriage return is typed. If the buffer fills to the maximum, additional keyboard input is ignored and a bell is rung until carriage return is entered. The second byte of the buffer is set to the number of characters received excluding the carriage return (which is always the last character) unless the buffer was full prior to the carriage return. Editing of this buffer is described below and is somewhat different from CP/M-80.

---> Copy one character
DEL Skip one character

SEL Copy until first occurrence of next character typed CLS Skip until first occurrence of next character typed

Copy to end of line

,ESC Kill new line HOME Re-edit line

K--, BS Backspace one character INS Toggle insert mode

Note that CP/M-80 does not place the terminating carriage return in the buffer and that this byte will be uninitialized. However, because the count of characters does not include the carriage return, the count returned is the same as that under CP/M-80.

- B Keyboard Status Check: If a character is available from the keyboard, A will return FFH. Otherwise A will be zero. If the available character is Control-C, Control-S, or printer echo, the appropriate action will be taken.
- C Disk Reset: Flushes all file buffers. Files that have been changed in size and not closed will not be properly recorded in the disk directory until they are closed.

Unlike CP/M-80 this function need not be called before a disk change if all files which have been written have been closed.

E Select Disk: The drive specified in E (0 = A, 1 = B, etc.) is selected as the default drive.

Unlike CP/M-80, if the disk is changed the drive does not revert to Read Only status. Also, the number of drives is returned in A.

F Open File: On entry. DE points to an unopened file control block (FCB). The disk directory is searched for the named file and A returns FFH if it is not found. If it is found, A returns zero. The extent field is used and the record count field is appropriately filled in. The size of the file (in - bytes), the modification date and time are set in the FCB from information obtained from the directory. It is the application's responsibility to set the record size to the desired size if it uses the block read and write calls. It is also the application's responsibility to set the random record field and/or the extent and current record fields.

Unlike CP/M-80, there is no concept of partial or missing extents in MSX-DOS. It is not possible to create a file with "holes" in it. Therefore, this function may not fail in all the cases CP/M-80 would. Note that different directory information is copied into bytes 10-1F4 of the FCB than in CP/M-80. Also, MSX-DOS always returns a zero if successful, whereas CP/M-80 returns a number from 0 to 3, indicating the position within the logical directory sector of this file.

10 Close File: This function must be called after file writes to ensure all directory information and the File Allocation Table is updated. On entry. DE points to an opened FCB.

Unlike CP/M-80, MSX-DOS assumes that the disk has been changed and A returns FFH. Otherwise, the directory is updated to reflect the status in the FCB and A returns zero.

11 Search First: On entry. DE points to an unopened FCB. The disk directory is searched for the first matching name (the name could have "?"s indicating any letter matched) and if none is found. A returns FFH. Otherwise 33 (as opposed to CP/M-80's 128) locations at the disk transfer address contain a valid unopened FCB with the first byte indicating the drive number used (1=A, etc.) and A returns a zero. The extent field returned will match the one that was searched for, with the record count initialized appropriately.

Unlike CP/M-80, the directory position returned is always zero (with CP/M-80 it can be 0 to 3). Also, if the drive field contains a "?", the file name and extent field are ignored, causing anything to match. Deleted directory entries are not accessible and looking beyond the first directory entry at the disk transfer address will not work. If the extent field is a "?", the resultant extent field is set to the highest extent and record count.

- 12 Search Next: After a Function 11 has been called and has found a match, Function 12 may be called to find the next match to an ambiguous request ("?"s in the search filename). Both inputs and outputs are the same as Function 11. No intervening calls should be made between Search First and Search Next or successive Search Next requests. Search Next assumes the address of the FCB used in Search First.
- 13 Delete File: On entry. DE points to an unopened FCB. All matching directory entries are deleted. If no directory entries match, A returns FFH. Otherwise, A returns zero.
- 14 Sequential Read: On entry, DE points to an opened FCB. The record addressed by the current extent and current record is loaded at the disk transfer address, then the record number is incremented. If end-of-file is encountered, A returns OlH. A returns zero if the transfer was completed successfully.

Unlike CP/M-80, which does not recognize record sizes other than 80H. partial records are zero-filled.

15 Sequential Write: On entry. DE points to an opened FCB. The record addressed by the current extent and current record is written from the disk transfer address, then the record number is incremented. If the disk is full, A returns with OlH. A returns zero if the transfer was completed successfully.

Note that in the case of records smaller than sector sizes, the sector is buffered up for an eventual write when a sector's worth of data is accumulated.

16 Create File: On entry. DE points to an unopened FCB. The disk directory is searched for an empty directory entry, and A returns FFH if none is found. Otherwise the entry is initialized to a zero length file, the file is opened (see Function F), and A returns zero.

Unlike CP/M-80, MSX-DOS always returns zero as the directory code, instead of 0 to 3. If the file already exists and the extent field contains a zero, MSX-DOS deletes the existing file. If the extent field is non-zero, the DOS opens the file and points to that extent.

17 Rename File: On entry, DE points to a modified FCB which has a drive code and filename in the usual position, and a second filename starting 6 bytes after the first (DE+11H) in what is normally a reserved area. Every matching occurrence of the first is changed to the second (with the restriction that two files cannot have the same name and extension). If no match was found, A returns FFH.

Wild cards may be used in both source and destination files. If "?" appears in the second name, then the corresponding position in the original name will be unchanged.

- 18 Login Vector: Returns 1 bit for all drives on the system in HL, with drive A the low-order bit.
- 19 Current Disk: A returns with the code of the default drive (0=A, etc.).
- 1A Set Disk Transfer Address: The disk transfer address is set to DE. On a Disk Reset (Function D) the disk transfer address is reset to 80H.
- IB FAT Address: A drive code is passed in E. On return, A contains the number of sectors per cluster for the default drive or FFH if the drive number is invalid. BC is sector size. DE is the number of clusters on the disk. HL is the number of free clusters. IY points to the FAT. IX points to the BPB.

CP/M-80 returns with HL pointing to a bit vector of free allocated clusters. The cluster size can be obtained from CP/M-80 Function 1F. No such structure exists within MSX-DOS.

- 1C Write Protect Drive: NOT IMPLEMENTED. This call will return with no processing.
- 1D Get R/O Vector: NOT IMPLEMENTED. This call with return with zeros, indicating no drives write-protected.
- 1E Set File Attributes: NOT IMPLEMENTED.
- 1F Get Disk Parameter Address: NOT IMPLEMENTED.
- 20 Set/Get User Code: NOT IMPLEMENTED
- 21 Random Read: On Entry. DE points to an opened FCB. The current extent and current record are set to agree with the random record field. This record is loaded at the disk transfer address. If end-of-file is encountered, A returns OlH. Otherwise, A returns zero if successful.

Unlike CP/M-80, which does not support them, partial records are zero-filled. The high-byte (r2) need not be zero and is always used, which addresses files up to 2 gigabytes.

22 Random Write: On entry, DE points to an opened FCB. The current extent and current record are set to agree with the random record field. This record is written from the disk transfer address. A returns OlH if the disk is full. Otherwise, A returns zero.

As with Sequential Write, the sector is buffered if the record size is smaller than the sector size.

23 File Size: On entry. DE points to an unopened FCB. The disk directory is searched for the first matching entry and if none is found, A returns FFH. Otherwise, the random record field is set with the size of the file in records, and A returns zero.

Unlike CP/M-80, MSX-DOS supports ambiguous filenames, using the first match.

- 24 Set Random Record: On entry, DE points to an opened FCB. This function sets the random record field to the same file address as the current extent and current record fields.
- 25 Disk Reset: NOT IMPLEMENTED. This call will return after no processing.
- 26 Random Block Write: Essentially the same as Function 27 above, except for writing and a write protect indication. If there is insufficient space on the disk. A returns OlH and no records are written. If HL is zero upon entry, no records are written, but the file is set to the length specified by the random record field, whether longer or shorter than the current file size. (Allocation units are released or allocated as appropriate.)
- 27 Random Block Read: On entry, DE points to an opened FCB, and HL contains a record count which must not be zero. The specified number of records (in terms of the record size field) are read from the file address specified by the random record field (3 bytes if sector size is greater than or equal to 40H; otherwise 4 bytes) into the disk transfer address. If end-of-file is reached, A returns OlH, zero filling any partial record. A returns zero on a successful read. In any case, HL returns the actual number of record read, and the random record field is set to address the next record.
- 28 Zero Fill Random Write: Same as call 22 except whenever a write request would extend a file contiquously, the space in between is zeroed as well as allocated.
- 29 NOT IMPLEMENTED
- 2A Get Date: Returns the date in DE. HL has the year, D has the month (1=Jan, etc.) and E has the day. A has the day of the week (0=Sun). If the time clock changes to the next day, the date will be adjusted accordingly, taking into account the number of days in each month and leap years.
- 2B Set Date: On entry. DE and HL must contain a valid date as described in Function 2A above. If the date is valid, A returns zero; otherwise, A returns FFH.
- 2C Get Time: Returns time of day. It has the hours, L has the minutes, D has the seconds. and E has the hundredths of seconds. This form is easily converted to a printable form, yet it can also be used to calculate (e.g. subtracting two times).

- 2D Set Time: On entry, DE and HL must contain a valid time as described in Function 2C. If the time is valid, A returns zero; otherwise A returns FFH.
- 2E Verify Read After Write: Supported
- 2F Direct Sector Read: Supported
- 30 Direct Sector Write: Supported

6. MSX-DOS FCB Format

The following explains the MSX-DOS File Control Block Format. The FCB is a 37-byte data area, with the following structure.

Offset	Function
0	Drive number. O=default. 1=A, 2=B,
1-8	Filename left justified with trailing blanks. All 8 bits of characters are significant. If the name of a device (PRN, CON) is placed here, do not include the optional colon.
9-B	Filename extension, left justified with trailing blanks (can be all blanks). All 8 bits of characters are significant.
С	Extent field. Used on Open, Create, Search, Sequential Read, and Sequential Write. Set by Random Read and Random Write.
D	S1. Reserved.
E	S2. An 8-bit extension of the extent field. Zeroed on Open, Create, and Search First. Used as low byte of record size for Block Read and Block Write.
F	Record Count. Normally 8DH, but set to number of 128-byte records left in extent after Open and Create. Incremented as appropriate by Sequential Write and Random Write. Used as high byte of record size for Block Read and Block Write.
10-13	File size in bytes. In this 2-word field, the first word is the low order part of the size.
14-15	Date the filenames were created or last modified.
	Bits F-9 (year) = 0-119 (1980-2099) Bits 8-5 (month) = 1-12 Bits 4-0 (day) = 1-31

16-17 Time the file was created or last modified.

Bits F-B (hours) = 0-23Bits A-5 (minutes) = 0-59

Bits 6-0 (seconds) = 0-29 (two second increments)

18-1F Reserved

Current relative record number (0-127) within the current block. You must set this field before doing sequential read/write operations to the disk. This field is not initialized by the Open function call.

21-24 Relative record number relative to the beginning of the file, starting with zero. You must set this field before doing random read/write operations to the disk. This field is not initialized by the Open function call.

If the record size is less than 64 bytes, both words are used. Otherwise, only the first 3 bytes are used. Note that if you use the File Control Block at 5CH in the program segment, the last byte of the FCB overlaps the first byte of the unformatted parameter block.
